ASTRONOMICAL

AND

METEOROLOGICAL OBSERVATIONS

MADE AT THE

UNITED STATES NAVAL OBSERVATORY

DURING

THE YEAR 1869.

PUBLISHED BY AUTHORITY OF THE
HON. SECRETARY OF THE NAVY.

COMMODORE B. F. SANDS, U. S. N.,
SUPERINTENDENT.

WASHINGTON:
GOVERNMENT PRINTING OFFICE.
1872.

TABLE OF CONTENTS.

INTRODUCTION.

OBSERVATIONS AND RESULTS.

APPENDICES.

REPORT OF THE SUPERINTENDENT OF THE OBSERVATORY TO THE CHIEF OF THE BUREAU OF NAVIGATION.

UNITED STATES NAVAL OBSERVATORY, *Washington, September* 25, 1869.

COMMODORE: I have the honor to present the following report of the operations of this establishment for the past year, with estimates, also, of the amount required for its support for the fiscal year ending June 30, 1871.

ASTRONOMICAL WORK.

The Equatorial Instrument, in charge of Professor Asaph Hall, U. S. N., was employed, as in precediing years, in the observation of asteroids, occultations, comets, &c., until the first of May last, at which time Professor Hall was detailed by the Department and ordered to Behring Strait, to observe the total eclipse of the sun of the 7th of August, and the work of the instrument was temporarily suspended. It will be resumed on the return of that officer, now daily looked for.

In view of the comparatively small size of the Equatorial Telescope, and its inferiority to many of its kind in this country, there is among those acquainted with the wants of the Observatory a strong desire that it might, as an important national establishment, be furnished with the best instruments that can be procured; and, sharing in this desire, I am induced to repeat here the recommendation on the subject in my report of last year.

"At the present time the deficiency of the Observatory, which would be noticed with most surprise, is the absence of a telescope at all comparable with many owned by colleges, observatories, and private individuals throughout the country. This will seem the more remarkable since the most successful living constructor of telescopes is an American—Alvan Clark, of Cambridge, Massachusetts. Mr. Clark has constructed not only nearly all the best instruments lately erected in America, but some of the finest in Europe. It is understood that he has been for some time desirous of receiving an order for the largest refractor in the world; but the great cost—$40,000 in gold—has hitherto deterred individuals from giving the order. But it seems eminently desirable and proper that the Government of the United States should employ at its Observatory such an instrument of the highest power. Considering that any smaller instrument than that proposed would soon be superceded, that several institutions of learning in the country are endeavoring to procure one of this high character, and considering that not more than one such can probably ever be undertaken by Mr. Clark, it will be seen that delay endangers our being ever able to command it. As the construction of the instrument will occupy some four years, it is not necessary that more than one-fourth of the cost should be appropriated in any one year."

Impressed with the conviction that the opportunity thus offered should be availed of by the Government, I recommend that Congress be asked to make an appropriation of forty thousand dollars, and the superintendent of the Observatory authorized to contract with Mr. Clark, in that sum, for the finest instrument that eminent artist is capable of producing; the amount so appropriated to be paid in four annual installments, each of ten thousand dollars, (gold.)

Transit Circle.—This instrument has been in charge of Professor Simon Newcomb, U. S. N., who has also superintended the erection of the new wing of the Observatory.

In my last annual report, the very grave defects of the observing-room, in which this instrument was mounted, were set forth, and an appropriation of five thousand dollars to build a new one, with a proper foundation for the instrument, was recommended.

The requisite appropriation was made by Congress, and in April last proposals to build the wing were duly advertised for, and the work was commenced about the end of May. It is now nearly completed.

The architectural qualities of the new room have not yet been tested, but there is no doubt that for purely astronomical purposes it is the best meridian observing-room in the world.

Of the five observers employed with the instrument at the date of my last report, one, Professor Eastman, was transferred to the east wing in January last; another, Professor Harkness, has been disabled from observing by ill-health during a large part of the year; and the junior aid had not sufficient experience to make the more difficult observations. Observations have therefore been generally confined to the more necessary ones, namely, those of the sun, moon, larger planets, and fundamental stars.

The work of copying the observations from the note-books for the press has been done by Captain Whiting and Professor Beecher.

In June last the instrument was dismounted to allow its piers to be used in the new wing. The work of remounting it is about to commence.

Certain defects have been found to exist in the object-glass of this telescope, which can only be removed by re-grinding, and I have accordingly asked an appropriation for that purpose.

The Transit Instrument and the Mural Circle have continued in charge of Professor M. Yarnall, U. S. N., who was assisted in the work of the former instrument, from the 1st of January until the 1st of July, by Professor J. R. Eastman, U. S. N., and after that time by Mr. Edgar Frisby, "aid."

These instruments were employed in observing stars whose places were wanting either in right ascension or declination, for the general catalogue; and since the dismounting of the Transit Circle, in observing the moon and such of the planets as came to our meridian.

The observers were engaged with the Transit Instrument for a few nights in exchanging time-signals for difference of longitude between Washington and Des Moines, Iowa, and between Washington and Bristol, Tennessee; the results of which will presently be stated.

Mr. M. H. Doolittle, the senior assistant observer or "aid," has had charge of the Mural Circle, under direction of Professor Yarnall, and is especially commended for industry by that officer. He was assisted after the first of May by Mr. F. W. Bardwell, "aid."

Professor Yarnall has been engaged, during office hours, in reducing and preparing for the press the Transit Observations of 1868, which remain only to be copied on sheets, when they will be ready for publication. He has also been engaged in collating and preparing stars for publication in the General Catalogue, the epoch of the catalogue (1860) being different from that (1870) to which the current observations are reduced.

The observations to be made with the Transit Instrument, for the Catalogue, are now nearly completed, as far as observing is concerned, but much time will be needed to finish the reduction of the observations and transfer them to the Catalogue.

The observations with the Mural Circle are not so nearly finished, and exclusive attention will be given to that instrument after such observations as remain to be made with the Transit Instrument shall have been finished.

Meteorology.—Professor Eastman has had the supervision of the meteorological observations made during the year.

The instruments used are a Mercurial Barometer, Dry and Wet-bulb, and Solar Thermometers, Rain-Gauge, and Wind-Vane; also a Mercurial Barometer, by Green, of New York, employed as a *standard*, and two Registering Thermometers, indicating maximum and minimum temperature.

The observations have, as usual, been made every three hours, night and day, by the watchmen, Messrs. Hays, Horigan, and Cahill, under the direction of the officer in charge of the work.

Owing to more pressing duties, only the observations for 1867 have been prepared for the press during the year, which was done with the assistance of Professor Nourse.

I have submitted an estimate for the purchase of certain meteorological instruments with which it is desirable to furnish the Observatory.

Chronometers.—The labors of the officers on duty in the chronometer department have been unremitting, and when it is considered that all the ships of the Navy, going to various parts of the world, are supplied with chronometers from this establishment, the importance of these labors can hardly be overrated.

The system of keeping a complete record of all the chronometers has been continued, and the late increase of officers, so much wanted heretofore, has enabled us to make satisfactory progress in the history of all the chronometers from the earliest period possible.

Commander William N. Jeffers was ordered on duty here in December last, and took charge of the chronometers, relieving Commander A. W. Johnson, who was detached the same month.

The following officers have also been on duty as assistants in this department: (1868,) Lieutenant

Commander J. H. Sands, from 19th September to 31st December; (1869,) Lieutenant Charles J. Train, from 1st January to 30th April; Lieutenant Commander E. J. Dichman, from 1st May, (under orders to Naval Academy, on 1st October;) Commander J. Young, from 15th May; Commander W. C. West, from 22d May; and Lieutenant Commander J. H. Sands, from 28th July.

It is desirable that at least three of the grade of officers who are to be navigation officers at sea should serve at least one year each at the Observatory, to become conversant with the care of chronometers and the requirements of the Observatory in the correct record of their performance.

In order to increase the knowledge of thermometric laws, and to enable the navigator of each ship to keep an exact record of the temperature of the chronometer-room on shipboard, a Registering Thermometer, previously carefully compared with the standard, is sent with each issue of chronometers to every ship.

It is a matter of gratification to be able to inform the Bureau that the chronometers manufactured in this country are superior, in point of finish and appearance, to the instruments made abroad, and in point of accuracy our home-made instruments are equal to the best and superior to the ordinary foreign chronometers. For the observation of the time of the solar eclipse, for which the greatest possible accuracy and regularity of rate was required, chronometers were used made by T. S. & J. D. Negus, of New York.

The number of chronometers now on hand in the receiving cases is one hundred and nine, (109,) of which nearly all are ready for immediate issue. They are wound daily at noon, and compared with a standard clock keeping mean time, the error of which is ascertained every five days, and every ten days the error and rate of each chronometer are computed and entered in the rate-books, from which the performance of any chronometer can be obtained at any time. Upon return from sea, each instrument is carefully examined, and, if found defective, is sent to the chronometer-maker for cleaning or repairs.

Every day a time-ball is dropped at the exact moment of mean noon, by means of an electric connection, giving the exact time to Washington and the surrounding country.

TELEGRAPHIC APPARATUS AND CONNECTIONS.

The electro-magnetic and telegraphic apparatus connected with the Observatory is under the charge of Professor William Harkness, U. S. N., assisted by Mr. W. H. Gardner, the instrument-maker, and has worked well.

There are three lines of telegraph running out of the building. The first line runs to the Navy Department, where it controls a clock, which is made to beat in unison with the marble-case mean-time clock of the Observatory, by means of the apparatus invented by Mr. R. L. Jones, of Wolverhampton, England. Correct time is thus furnished to the Department, the working of the apparatus continuing in all respects satisfactory.

The second line of telegraph runs to the Washington Fire-alarm Telegraph Office. It puts us in connection with the fire-bells, and is used to furnish correct time to the city by striking them daily at seven a. m., twelve m., and six p. m.

The third line of telegraph belongs to the Western Union Telegraph Company, and is a loop from the wire which they designate as No. 7 south. By means of it are distributed the time-signals which serve to regulate the clocks of nearly all the railroads in the southern States. They are sent during the four minutes between 11.57 a. m. and 12.01 p. m., as follows: Daily to the Baltimore and Ohio Railroad, Baltimore City, and the other principal cities on their line, as far as New Orleans.

By the kindness of the Western Union Telegraph Company, we have had the free use of their wires to determine the longitude of four points during the past year.

At the request of the Spanish government, time-signals were, between September 8 and September 21, 1868, exchanged on four nights with Lieutenant C. Pujazon, of the Spanish navy, stationed in the arsenal grounds at Havana, Cuba. These signals place the station

$$0^h \quad 21^m \quad 12^s.58 \pm 0^s.035$$

west of center of dome of this Observatory.*

On the night of April 7, 1869, time-signals were exchanged with a United States Coast Survey party stationed at Staunton, Virginia.

* For full details of this work, see Appendix I to the volume of Observations for 1867.

On five nights, between July 26 and August 7, time-signals were exchanged with the Observatory party sent to Des Moines to observe the eclipse of August 7. These signals place the station at Des Moines

$$1^h \quad 6^m \quad 16^s.05 \pm 0^s.05$$

west of center of dome of this Observatory.

On three nights, between July 29 and August 7, time-signals were exchanged with a United States Coast Survey party, stationed at Bristol, Tennessee, and the result is that their station was

$$0^h \quad 20^m \quad 32^s.74$$

west of centre of dome of this Observatory.

THE TOTAL ECLIPSE OF THE SUN OF AUGUST 7.

Early in spring preparations began to be made here for the observation of the total eclipse of the sun of the 7th of August, an event of rare occurrence, and, fiom the important results to be derived from accurate observations, exciting among astronomers the liveliest interest.

The first party sent out from the Observatory consisted of Professor Asaph Hall, United States Navy, and Mr. Joseph A. Rogers, of the Hydrographic Office, who were detailed by the Department early in May, and ordered to proceed to Behring Strait, to a station there to be selected. The party reached San Francisco in June, and sailed on the last of that month for the strait in the United States steamer Mohican.

Accounts from San Francisco inform us that the expedition arrived at Plover Bay in ample time, and that every preparation was made for the observations, which were only partially successful, on account of the obscuration of the sun by clouds during the time of the eclipse. I feared this from the first, but observations at that location were so important as to prompt us to risk the chance of failure.

On the 14th of June the Department also detailed Professors Newcomb, Harkness, and Eastman to proceed to Des Moines, Iowa, a point on the line of totality, and select a suitable station for the purpose of observing the eclipse.

Mr. Bardwell, aid, was sent to Bristol, Tennessee, for observations at that point.

Surgeon General Barnes kindly detailed Assistant Surgeon Brevet Major Edward Curtis, of the Army, a gentleman skilled in photography, to accompany our Des Moines party. Previous to their departure, a little temporary frame building was erected in the grounds, as a practice observatory for photographing, &c., in which was mounted the Equatorial Telescope of the Naval Academy, kindly loaned by Vice-Admiral Porter, for observations of the eclipse. Arrived at Des Moines, the party selected stations, set up their instruments, and made all the needful preparations.

The weather on the day of the eclipse was favorable, and the observations were most successfully made.

The officers of the expedition, since their return to the Observatory, have been engaged upon their reports, the preparation of which involves some labor; and it will yet be some days before they are finished.* The results will prove highly interesting to the scientific world, and showing the large share the Observatory has had on this important occasion, will sustain the reputation the institution has already attained.

THE LIBRARY.

The Library is in charge of Professor J. E. Nourse, United States Navy. The annual volume of Astronomical and Meteorological Observations for the year 1866, forming a quarto of 472 pages, issued from the Government press in May last. The distribution of these volumes was begun on the day of their delivery to the Observatory. Five hundred copies in all were published. The demand for the observations by observatories and other scientific institutions, and by individuals, has left on hand a smaller number than ought justly to be reserved for the future supply of new observatories and institutions. The number of copies has been, therefore, increased for the volume now in press.

The Observatory is again indebted to the kind offices of the resident foreign legations, the Department of State, and the Smithsonian Institution, for the safe and prompt delivery of the volumes sent aboard. The calls continue for the separate reports upon the meteoric shower of November, 1868, the West India cyclone of 1867, and upon the routes for inter-oceanic canals and railroads.

* These reports have been published as Appendix II to the volume of Observations for 1867.

The additions to the Library, through its exchanges with other institutions, and with individuals eminent for scientific research, at home and abroad, have been of a very valuable character, and are still steadily increasing in number.

In case of a vacancy in the number of professors attached to the Observatory, the law of April 17, 1866, prohibiting the further appointment of professors of mathematics in the Navy, would cripple the Observatory to supply his place without further legislation.

I would suggest some modification of the law in regard to the professors at the Observatory, who are the astronomers and observers; and further to provide an increase of pay for every five years of service at this institution, in that capacity, as compensation for faithful and efficient service, and to hold out some inducement or promotion to retain an efficient corps of astronomers.

In speaking of the work of the Observatory, I must not omit to commend the three assistant observers, or "aids," allowed by law to the Observatory, for their zeal, intelligence, and industry in performing all the duties assigned them. These gentlemen, before being appointed, were required to undergo a strict examination as to mathematical attainments and knowledge of general science, and to prove their fitness for appointment by a high standard. They are frequently required to perform the duties of observer as well as computer, the more experienced observing on alternate nights with the professors. Considering, therefore, the value of their services, I earnestly recommend a small increase of the pay of the three assistant observers, or "aids." They now receive at the rate of $1,333 33 each, per annum; ($4,000 for the three.)

I recommend that their pay be graduated or classified as follows:

First aid, or assistant observer	$1,600 per annum.
Second aid, or assistant observer	1,500 per annum.
Third aid, or assistant observer	1,400 per annum.

The rewarding of meritorious service wherever and by whomsoever performed, is a just principle, always recognized and observed by our Government when a proper occasion for its exercise is presented. I believe the recommendation above affords such an occasion, and I hope it will meet with favor.

Very respectfully, your obedient servant,

B. F. SANDS,
Commodore, Superintendent.

Commodore JAMES ALDEN, U. S. N.,
Chief of Bureau of Navigation, Navy Department.

INTRODUCTION.

This Observatory was originally built as a depot of charts and instruments for the Navy, the work being done under supervision of Lieutenant James M. Gilliss, U. S. N., and a very full account of it is given in his "Report on the Plan and Construction of the Depot of Charts and Instruments, with a description of the Instruments, &c.," made to the Secretary of the Navy in February, 1845, and published as Senate Document No. 114, Twenty-eighth Congress, second session. A more general description, illustrated by plans of the building and drawings of the principal instruments, is contained in the volume of Washington Observations for 1845; and an account of the changes made for the reception of the large Transit Circle, together with a detailed description of that instrument, will be found in the volume of Washington Observations for 1865.

Position of the Observatory.—The latitude deduced from observations made with the Mural Circle in 1845 and 1846 was $+ 38° 53' 39''.25$;* and that value has been employed in the reduction of all observations made with the Mural down to the present time. The observations made with the same instrument from 1861 to 1864, inclusive, give a latitude $0''.47$ less, viz: $+ 38° 53' 38''.8$;† and this latter value is the one which has always been used in computing the published "Apparent North Polar Distances" obtained from observations made with the Transit Circle. It should be remarked, however, that in the published tables of "Right Ascensions, North Polar Distances, and Semi-diameters of the Sun, Moon, and Planets, deduced from Observations with the Transit Circle," and of "Corrections to the Right Ascensions and North Polar Distances of the American Ephemeris given by individual observations of Stars with the Transit Circle," the final north polar distances depend upon the position of the pole determined from all the observations of circumpolar stars made with the Transit Circle during the same year as those contained in the tables in question. The adopted longitude of the Observatory from Greenwich, used in interpolating tabular positions of the Moon and Planets, is $5^h\ 8^m\ 12^s.0$.‡

Arrangement of Work.—The system which has prevailed since the revival of the astronomical activity of the establishment in 1861, is still continued. Under this system, the observations with each instrument are directed by the officer having charge of it, who is held responsible for the proper performance of the work, and prepares the descriptions, explanations, and discussions of the observations contained in the annual volumes.

During the year 1869 the division of labor was as follows:

The Equatorial was in charge of Professor Asaph Hall, U. S. N.

The Transit Circle was in charge of Professor Simon Newcomb, U. S. N., who was assisted by Professor William Harkness, U. S. N., and by the following-named assistant observers during the periods specified, viz: Mr. Charles Thirion, from January 1 to May 1, and Mr. Edgar Frisby, from January 1 to June 15. The copying of the work from the original observing-books and reduction-sheets on to the sheets for the printer, was done by Captain William B. Whiting, U. S. N.

The Transit Instrument and the Mural Circle were in charge of Professor M. Yarnall, U. S. N., who was assisted by the following-named officers during the periods specified: In the work with the Transit Instrument, by Professor John R. Eastman, U. S. N., from January 1 to July 1; Assistant Observer Edgar Frisby from July 15 to October 8; and Assistant Observer F. W. Bardwell from November 10 to December 31; in the work with the Mural Circle by Assistant Observer M. H. Doolittle throughout the year; Assistant Observer F. W. Bardwell from June 12 to November 11; and Assistant Observer Edgar Frisby from October 9 to December 31. The reductions were checked by Professor Mark H. Beecher, U. S. N.

* Washington Observations for 1845; Appendix, p. 116.

† Washington Observations for 1864; Introduction, p. xliv.

‡ In some previous volumes this longitude is erroneously given. All the tabular positions of the Moon since 1860 have been computed with the adopted longitude $5^h\ 8^m\ 12^s.0$.

The department of chronometers, which includes the dropping of the time-ball at noon, and the transmission of time-signals to the city through the Police Telegraph, was in charge of Commander William N. Jeffers, U. S. N., from January 1 to November 16; and in charge of Commander J. Young, U. S. N., from November 16 till the end of the year. The following-named officers acted as assistants in this department during the periods specified, viz: Lieutenant Charles J. Train from January 1 to April 30; Lieutenant Commander E. J. Dichman from May 1 to September 30; Commander J. Young from May 15 to November 16; Commander W. C. West from May 22 to December 31; Lieutenant Commander J. H. Sands from July 28 to December 31; Ensign R. Clover from October 1 to December 31; Master Frank Turnbull from October 22 to December 31.

The Meteorological Observations were made under the supervision of Professor J. R. Eastman, U. S. N., by the watchmen of the establishment, Messrs. Thomas Hays, Dennis Horigan, and Nicholas Cahill.

Mr. William F. Gardner, instrument-maker, executed all necessary alterations and repairs to the instruments during the year.

Mr. Thomas Harrison, clerk and disbursing officer, had charge of the official correspondence and accounts of the establishment.

The Observatory, being a naval establishment, is under the general supervision of the Bureau of Navigation of the Navy Department.

THE TRANSIT CIRCLE.

During the year 1869 this instrument was employed on the stars of the American Ephemeris and the bodies of the solar system. In the month of June the instrument was dismounted to be removed to an improved observing room, and was not again used during the year.

CONDENSED DESCRIPTION.

For a detailed description of the instrument, with an investigation of its constants, reference may be had to the Washington Observations for 1865. The following condensed description will suffice for the explanation of the observations and their reductions:

The instrument is furnished with two circles, each divided to every 2′ of arc, and read by four microscopes. The circle on the clamp end of the axis, called circle A, has also a coarse division to every 10′ for setting. The division is read by a single horizontal microscope of low power. The readings of the two circles increase in opposite directions, so that their sum is a constant as the instrument revolves. The microscopes on the west pier are numbered I–IV; those on the east pier V–VIII. The readings of the former diminish and those of the latter increase as the telescope moves from the zenith toward the south. Each revolution of the microscope micrometers measures 30″ of arc.

The instrument is reversible, and each circle can be fastened in any required position relatively to the telescope.

Till the end of 1868 the reticule had twenty-three vertical and two horizontal fixed wires.* At the beginning of 1869 a new system of wires was put into the same scores, but the four close wires near each side of the field were omitted. In 1869 the instrument had therefore only fifteen vertical wires. Several determinations of the intervals of the new wires were made, but they differed so little from those of the old wires that the latter were adopted in the reductions. They are as follows, the notation of the actual wires being the reverse of that employed in 1868, the numbers or letters being employed in the order of transit of an equatorial star, whether the clamp be east or west:

	s.		s.		s.
I	+ 36.727	C_1	+ 4.060	D_1	− 8.150
II	+ 24.465	C_2	+ 2.025	D_2	− 9.661
		IV = C_3	− 0.008	V = D_3	− 12.253
III = B_1	+ 12.229	C_4	− 2.031		
B_2	+ 9.679	C_5	− 4.085	VI	− 24.465
B_3	+ 8.173			VII	− 36.723

Eye-piece Micrometers.—A single vertical wire is moved in R. A. by a micrometer screw. It serves for the determination of collimation error, and is sometimes used for observations of the transit of Polaris, when clouds prevent observations at the fixed wires. Each revolution measures $1^s.020$.

The Z. D. micrometer carries four horizontal wires. The middle two form a close pair, distant about 4″.6, the mean of which is regarded as the standard middle wire. The other two are placed at a distance of about ten micrometer revolutions on each side. That nearest the micrometer head is called wire A; the other, wire B.

The readings of both micrometers increase as the wires move from the head, and the position of the head of the Z. D. micrometer is such that an increase of reading is subtractive from the reading of circle A and additive to that of circle B. When the observer looking into the telescope has circle A on his right, the micrometer head is below the eye-piece. During 1869 this was the position when the telescope pointed south and the observer looked south.

* Description of the Transit Circle, § 32.

Collimators.—The instrument is furnished with two collimators, of which the object-glasses have each $2\frac{1}{4}$ inches aperture and 35 inches focus. Each end of a collimator projects 6 inches beyond the supporting pivots, which are only 23 inches apart. The collimators are interchangeable in position. Each is furnished with a delicate spirit-level, by which its axis of sight may be leveled. Collimator A has in its focus a pair of wires 10″ apart in one direction, and a single wire crossing them. Collimator B is furnished with a simple pair of rectangular cross-wires.

Each side of the central cube of the telescope is pierced with a circular opening $2\frac{1}{2}$ inches in diameter. Each opening is closed by a cap which screws into it. By unscrewing the caps and setting the telescope vertical, the wires of either collimator may be seen through the other.

The Sympiesometer.—This instrument was made by James Green, of New York. Its use is designed to lessen the number of observations and computations necessary in the determination of the correction to the refraction on account of the density of the air. It consists of a vertical tube, the top of which expands into a bulb, while the bottom is bent round in the form of a letter U. The large arm or cistern of the U holds sulphuric acid, and is closed by connection with an air-tight bag of oiled silk. The rest of the tube contains air. The quantity of air is so adjusted that in the hottest weather it nearly fills the vertical tube, while in the coldest weather the acid rises nearly to the bulb. If, now, the density of the fluid were zero, the density of the air within the bulb and tube would be the same as that of the external air. And, at all zenith distances at which it is worth while to observe for the determination of star positions, the refraction may be regarded as a function of the zenith distance and the density of the air simply. But, the sulphuric acid being quite a dense fluid, its height in the tube of the sympiesometer will be a function of any two of the three quantities, barometric pressure, temperature, and density of the external air. Since the datum wanted is the density of the external air, we shall express this density as a function of the height of the sympiesometer and barometer. Let us use the following notation:

B = height of barometer.

τ = temperature, counted from the absolute zero.

D = actual density of external air.

D_0 = density of air when the surfaces of the fluid in the tube and in the cistern are on the same level.

c = constant of elasticity of air.

l = total capacity of tube and bulb, counted from the point at which the surfaces of the acid in the cistern and tube are on the same level, measuring that capacity by the length to which it would be necessary to extend the tube in order that it might hold as much as the bulb.

h = height of internal surface of acid, counted from the same point with l.

a = specific gravity of acid, increased in the ratio of the bore of the tube to that of the cistern, specific gravity of mercury being unity.

B' = pressure of the confined air, in inches of mercury.

Then, from well known properties of elastic gases, we derive the equations,

$$B = c\,D\,\tau$$
$$B' = c\,D_0\,\tau\,\frac{l}{l-h}$$
$$B' = B - ah$$

From the last two equations,

$$B = ah + \frac{c\,D_0\,\tau\,l}{l-h}$$

Substituting for τ its value from the first equation, we find,

$$D = D_0\,\frac{l}{l-h}\,\frac{B}{B-ah}$$

Thus, D is expressed as a function of the height of the fluid in the sympiesometer, and of the height of the barometer. Let us put $B = B_0 + \beta$, B_0 being the mean height of the barometer, and β its small changes. Then, developing to the first powers of β, we have,

$$\frac{B}{B-ah} = \frac{B_0}{B_0-ah} - \frac{ah\beta}{(B_0-ah)^2}$$

To estimate the value of the last term of this equation we remark that—

The value of a is, roughly, about	$\frac{1}{8}$
The value of β seldom exceeds, during fine weather, ...	$\pm$ 0.4 inch.
The value of h rarely exceeds	8 inches
While we may put B_0	= 30.15

Consequently, the last term of the equation will rarely amount to $\frac{1}{2000}$, and may therefore be neglected, except in rare and exceptional cases. Neglecting it, we find,

$$D = \frac{B_0\, l\, D_0}{(B_0 - ah)\,(l - h)}$$

so that the density of the air is expressed as a function of the observed height of the sympiesometer, and of determinable constants.

Considering, however, that it was doubtful whether the invariableness of a and D_0 could be relied on for long intervals of time, it was deemed best not to attempt the direct determination of D, but to graduate the scale of the sympiesometer by comparison with the results of the thermometer and barometer. A scale was attached to the sympiesometer, the reading of which gave an approximation to the logarithm of the density of the air, the density at 29 inches and 100° being unity. A table of corrections to this scale was deduced from comparisons with the barometer and thermometer at various densities of the air.

USE OF THE TRANSIT CIRCLE.

Position of Axis.—The plan of work with the instrument contemplates its reversal at the beginning of each calendar year, and the use of a single circle in an invariable position, with a single set of four microscopes during each year. In the alternate years in which the axis is in the same position, the position of the circle used will be so changed that the polar distances of the stars will depend on different circle divisions in different years. It was therefore reversed at the beginning of the year 1869, and the zenithal reading of circle B was diminished 30′.

Arrangement of Observers.—As a general rule, one observer is charged with all the observations to be made during a definite twenty-four hours, which is considered the "observing day." The regular observing day begins at 9 o'clock a. m.; but when a special observation is to be made at an earlier hour in the morning, the observers may arrange among themselves to have the tour of duty commence earlier. An isolated observation, occurring at an inconvenient hour for the regular observer of the day, is frequently assigned to another.

Mode of Observing.—The telescope is set so as to bring some division of the circle under or near the zero of the microscopes. The subdivision of each 2′ of zenith distance thus depends entirely on the Z. D. micrometer. The bisections of a star in zenith distance are usually made as it crosses wires I, II, VI, and VII, by bringing its image midway between the middle pair of wires of the micrometer. Before each bisection the micrometer is drawn back so that the bisection shall always be made by moving the micrometer-screw forward. Bisections of stars whose polar distance is between 5° and 20° are frequently made at wires B_1, B_3, D_1, and D_3. Stars within 5° of the pole are usually bisected at the wires of set C. In the case of very faint objects, it was found impossible to bring the images between the close wires with accuracy, and such objects are therefore usually bisected with wire A or B. The micrometer readings are recorded, after the observation is completed, by means of the self-registering indexes.*

The transits of stars more than 5° from the pole over sets B, C, and D, are recorded by the electro-chronograph. Stars within 5° of the pole are observed by eye and ear, generally over the wires of set C, using the beat of the chronograph-pen.

It will be seen that by the adopted method of observation of quick-moving stars, the attention of the observer is occupied with the determination of but one co-ordinate at a time.

In the case of the sun the transit of the first limb is observed over the usual wires. The telescope is then clamped on one of the horizontal limbs, the image of which the observer brings between the micrometer wires at vertical wires I and II, while a second observer reads the microscopes. The telescope is next clamped on

* Description of the Transit Circle, § 30.

the opposite limb, which is measured at vertical wires VI and VII, while the second observer again reads the microscopes. The telescope is then unclamped and the transit of the second limb observed as usual.

When the second limb of the moon is to be observed the circle reading for the full horizontal limb is computed beforehand, the circle is set accordingly, and the microscopes are read before the moon enters the field. Five measures of the limb, if practicable, are then made as it crosses the field. The telescope is immediately unclamped and set on the second limb, the transit of which is observed in the usual way.

Arrangement of Clocks and Chronograph.—All the observations are recorded in time of the Kessel's clock. This clock has a gridiron pendulum, and its rate is tolerably regular. Its beats are recorded by a galvanic current in the way heretofore employed at this Observatory. To avoid any possible effect upon its rate, the mercurial connection is made near the middle of the rod, and the globule of mercury is made adjustable by being forced up from a small reservoir by a screw. It is kept quite small, and of such a height that the knife-edge just grazes its surface without causing any sensible vibration of its mass.

In February, 1867, fearing a possible diurnal inequality in the clock-rate during the summer months, arising from the diurnal change of temperature to which it would then be exposed, the clock was taken from its place in the superintendent's room and placed in a niche in the base of the pier of the great equatorial. The diurnal inequality of temperature is here insensible, and the annual inequality small. During warm weather it is exposed to dampness from condensation of the moisture of the air. To guard against this it was surrounded by quicklime. Unfortunately this substance was found, in slaking, to diffuse itself in the form of an impalpable dust, which penetrated the clock-case, and settled on the wheels. Its use had therefore to be discontinued and chloride of calcium to be substituted.

In the observing-room is placed a "counting-clock," regulated to run with the Kessel's clock, and thus serve to indicate the second corresponding to each beat of the latter, as indicated by the chronograph-pen. It is adjusted every day, on commencing observations, to beat coincidently with the chronograph-pen, but the sound of its beat is never employed in observation.

The transits are recorded on the cylinder chronograph, described in previous volumes of the observations. At each interval in the observations exceeding ten or fifteen minutes, the chronograph is stopped, and the hour, minute, and second of the last beat is taken from the face of the counting-clock and marked on the sheet. It was also intended that at least one other such indication of the clock-beat should always be marked on the sheet while the chronograph was still running, but in this the observers were frequently remiss. Errors of one second or one minute in the record therefore occur occasionally.

Determination of Error of Collimation.—This constant is determined from the opposing collimators, without reversal of the instrument. The covers of the opening through the cube of the telescope being removed, the latter is set on collimator A. One Y of the collimator is then so adjusted in azimuth that the middle wire of the telescope shall be about midway between the images of the parallel wires of the collimator. The observer can make this adjustment by viewing the reticule of the telescope through the collimator. The small deviation of the middle wire of the telescope from the mean of the collimator images is then measured with the R. A. micrometer. This measure is made by first so setting the micrometer wire that the mean of it and the fixed wire shall coincide with the mean of the images, and then moving it so as to coincide with the fixed wire. The required deviation is then one-half the space passed over. If, as is generally the case, the movable wire is almost in contact with the fixed one at the first setting, it is moved to an equal distance by estimation on the other side of the fixed wire. The required deviation is then one-fourth the space passed over.

The telescope is then pointed toward the zenith, and the observer brings the vertical wire of collimator B midway between the parallel wire images of collimator A.

The telescope is then pointed on collimator B, and the double distance of its wire image from the middle wire of the telescope is measured by first setting the movable wire so that the image shall be midway between it and the fixed wire, and then making it coincide with the latter. If, however, the image is very close to the wire, the first setting cannot be made with precision. In this case the telescope is clamped, and one of the single wires of the Z. D. micrometer is set alternately above and below the image of the horizontal collimator wire at a distance equal, by estimation, to that of the vertical fixed wire from the vertical image.

The telescope being again pointed toward the zenith, the observer looks into collimator A, and sets it independently on collimator B. Another set of measures is then made like the first. The mean result of the first and last set is taken as the concluded distance of image A from the middle wire.

Error of Level.—Two modes of determining this constant have been employed, namely:

(1.) Measurement of the distance between the middle wire and its image reflected from mercury when the telescope is pointed toward the nadir. This method was only employed three or four times, and then only as a check.

(2.) Use of the spirit-level. In each determination by this method four readings of the level are made, the latter being reversed between each pair of readings. The constant difference in the results of the two methods seems to be very small.

The separate results of the individual determinations of collimation and level errors are given at the end of this introduction.

Zenith Point Correction.—During the year 1869, this constant was determined by observations of the nadir point.

The use of the collimators for this purpose was entirely discontinued after June 1, 1867, it being found that the nadir observations could be made in the day-time nearly as well as at night. The process was the same as that described in the volume for 1866.

In observations of the nadir point, the microscope micrometers are read both before and after the measures with the Z. D. micrometer. The reading of the latter for coincidence of the close pair of wires with their reflected images is deduced from pairs of readings when the wires are so set that a reflected image is seen alternately north and south of a wire at a distance equal, by estimation, to the distance between the wires, or from similar pairs made when the wires and their two images form three equidistant spaces. Generally, two determinations are made by each method, and the mean of the results used.

EXPLANATION OF THE PRINTED OBSERVATIONS WITH THE TRANSIT CIRCLE.

General Remark.—In printing the observations the rule has been adopted to print every observation exactly as recorded by the observer, without alteration in any case whatever, and without addition, except in very rare cases, which are noted at the foot of the page. If a record seems erroneous, the error is pointed out in the foot-notes if it appears necessary so to do. Where there is no reasonable doubt of the nature of an error, a corresponding correction is introduced at such stage of the reductions as is most convenient. It has not been found practicable to adhere to any invariable rule respecting the point of introduction of the correction.

Detailed Explanation.—The first three columns need no explanation.

Column "*Observer*" gives the initial of the observer, as follows:

N.—Professor S. Newcomb.
H.—Professor A. Hall.
Ha.—Professor William Harkness.
T.—Mr. Charles Thirion.
F.—Mr. Edgar Frisby.

Column "*Weight*" indicates the quality of the observation as estimated by the observer. The weights are arranged on a scale from 1 to 5 as follows:

1 indicates a very bad or unsatisfactory observation.
2 indicates a poor one.
3 indicates an average one.
4 indicates a good one.
5 indicates a very good one.

The weights depend mainly upon the definition, steadiness, and distinctness of the image. When two numbers are given in this column the first refers to the observation of transit; the second to that of zenith distance.

Seconds of Transit over Wires.—In the case of stars more than 5° from the pole the times of transit usually recorded are those over the nine wires B_1 to B_3, C_2 to C_4, D_1 to D_3, which are regarded as the wires for regular observation. If the observation is irregular the wires observed can nearly always be inferred from the intervals between the transits. A frequent case is that of a transit over set C, and only one of the sets B or D. The former is then pushed aside one column from the middle to make room for the latter, so that a transit over B and C is found in columns I to VIII, and one over C and D in columns II to IX. Stars within 5° of the pole are observed by eye and ear, generally over the five wires of set C. The

seconds are then found in columns III to VII. Transits below the pole are recorded in an order the reverse of that actually observed, so that any one wire is found in the same column it would occupy if the transit were above the pole.

Mean Wire.—The imaginary wire to which all the observations are reduced to find the times given in this column is the mean of the nine regular wires mentioned above. When these wires are all observed their mean is taken. In other cases each wire is reduced separately and the mean of the reduced times taken. In most cases these reductions are facilitated by Tables I and II,* which give for each standard polar star, and for each degree of N. P. D. exceeding 30°, the reduction from each individual wire, frequently used, to the standard mean wire. In broken observations of the sun and planets this reduction is further corrected for motion of object in R. A., as given in the Ephemeris. In the case of the moon the reduction is computed from Tables III and IV†, which are founded on Airy's formula. Table III gives, for the latitude of Washington, the logarithm of the factor

$$\frac{\sin ☽\text{'s Geoc. Z. D.}}{\sin ☽\text{'s App. Z. D.}}$$

Table IV gives the logarithm of the factor

$$\frac{60m. + I}{60m}(1 + a)$$

I being the increase of the moon's mean time of transit in one hour of terrestrial longitude, as found in section "Moon Culminations" of the American Ephemeris, and a the ratio of acceleration of sidereal on solar time.

Correction for Instrument.—In this column is given the sum of the corrections for collimation, level, and azimuth. The table of adopted instrumental constants will be found at the end of the Introduction. (Table C.)

In the first column of this table we have the mean date, and, where necessary to the identification of short intervals, the tenth of a day. Where no tenth is added, the day commences with the tour of duty of the observer, generally about 3^h earlier than the commencement of the astronomical day. The constants for the nth day at 21^h mean time will therefore be found in the line $n + 1$. The letters d, n, indicate that observations were made during the day only, or the night only, indicated by the date. Column "Temp.," gives the approximate mean temperature Fahrenheit during the observations, and is used to compute the collimation.

Column c gives the adopted constant of collimation, concluded from the observations of collimation error, already explained. This constant is a function of the temperature, decreasing by $0^s.01$ for every rise of 3° Fahrenheit in the temperature. The adopted constants are therefore made to depend on the mean temperature of the atmosphere during each day, roughly derived from the Meterological Journal.

Column b gives the adopted level constant derived from the separate observations of level already explained. When transits of the reflected images of stars are observed, it is essential that the level constants should be known with precision, in order that they may be compared with transits observed directly. The level error has therefore been determined with more care on the dates of such observations.

Column a gives the adopted horizontal azimuth of the instrument. It has been derived almost entirely from the observed transits of the standard polar stars, Polaris, δ Ursæ Minoris, and λ Ursæ Minoris, in the following way:

If double transits of any of those stars were observed by one observer, the azimuth generally depends on them alone. When no such pair of transits was available, the azimuth is the mean result of all the single transits. The computation was, in all cases, conducted as follows: The time of each observed transit to be used for azimuth was first corrected for collimation, level, and clock error. A sufficiently close value of the latter correction was derived from transits of equatorial stars. The time of transit thus corrected was compared with a computed right ascension of the star.

On discussing the observations of 1866 and 1867 it was found that there were well-marked personal differences between the right ascensions of close polar stars deduced from the work of the different observers. The computed right ascensions were therefore obtained by applying to the positions of the American

* Found in the Washington Observations for 1866, pp. xxix and xxx. † Ibid., p. xxxi.

Ephemeris corrections depending on the observer, as shown in the following table. In the case of H., E., and F. no data for the correction were available; the correction employed is therefore that deemed nearest the absolute truth:

	Polaris.	δ Urs. Min.	51 Cephei.	λ Urs. Min.
	s.	s.	s.	s.
Observer N.	+ 0.8	− 0.4	+ 0.6	− 0.4
Observer H., E., or F. .	+ 1.0	0.0	+ 1.0	0.0
Observer T.	+ 2.2	+ 0.6	+ 1.6	+ 1.2

The difference between the corrected time of transit and the computed right ascension of the star was considered as due to azimuth, a value of which constant was deduced by multiplying the difference by the proper factor. In case of a pair of opposite transits, the mean result is adopted for the day. This mean is nearly independent of the adopted right ascension of the star, since a change in this element will produce opposite and nearly equal effects upon the two azimuths.

Table V* gives a condensed summary of factors by which the instrumental constants must be multiplied to obtain the correction to the time of transit, which will serve for the general purpose of verification. The tables in actual use are much more extensive, giving the required corrections for each degree of Z. D. and each .01 of the instrumental constants.

The *Apparent Clock Correction* is given only for direct observations of stars of the American Ephemeris within 40° of the equator. It is found by subtracting the sum of columns *Mean Wire* and *Instrument* from the computed apparent right ascension of the star. The latter is found by applying to the positions of the Ephemeris the corrections derived from the four years' observation with the transit instrument, 1862 to 1865, inclusive. They are found in Table D.

Adopted Clock Correction.—The apparent clock corrections derived from all the observations made by one observer in the course of his observing day are added up, and the mean taken. This mean is supposed to correspond to the mean of the times of observation. Both means are given in Table E, which also exhibits the computations of clock rate. The first column of this table gives the mean date, to which is added the tenth of a day when the time falls in the forenoon. The next two columns give the mean sidereal hour to the nearest tenth, and the mean clock correction. The small letters after the latter indicate the observers from whose observations the corrections were derived. In the next column the means are corrected for personal equation, and, in some instances, errors of an integral number of seconds in the counting clock.

The personal equation is derived from all the observations made during a period of three or six months. Equations of condition are formed by interpolating two corrections depending on the same observer at an interval not exceeding three, or, at the utmost, four days, on the supposition of a uniform rate, and comparing the interpolated values with the corrections given by other observers. The uniformity of the clock rate was such that all needful accuracy could be obtained by this method. The corrections to be applied to the clock corrections to reduce them to a uniform standard were thus found to be as follows:

	s.
N. (E. & E.)	− 0.24
N.	− 0.03
F.	+ 0.04
T.	+ 0.07

In the next column we have the daily rates for the intervals of the determinations, which are found by dividing the changes of reduced correction by the intervals.

Next, we have the adopted daily rates for each series of observations, which are derived from the observed rates preceding and following. In this determination a greater weight is given to a rate depending on an interval of one day than to one depending on a greater or less interval. Moreover, where there is much uncertainty in the rate, preference is given to multiples of 3 or 6 in adopting a rate.

* Found in the Washington Observations for 1866, p. xxxii.

The *Adopted Clock Corrections* are obtained by carrying the mean error for the observer forward or backward through his series of observations with the adopted rate. The occasional corrections for isolated observations are obtained by interpolating the corrected error between the nearest dates, on each side, and applying personal equation.

The *Apparent Right Ascension* is formed by applying the adopted clock and instrumental corrections to the time of transit over mean wire. It is therefore, in all cases, the right ascension of that part of the object actually observed.

Column *Miscellaneous Corrections* gives—

α. In the case of stars whose apparent positions are given in the American Ephemeris, the corrections to the right ascensions in the Ephemeris given by the observation.

β. In the case of other stars, the reduction to the mean position for the fictitious epoch 1870.0. This reduction is computed with the constants of precession, nutation, and aberration employed in the American Ephemeris, and no proper motion is applied.

γ. When only one limb of a planet is observed the sidereal time of its semi-diameter passing the meridian, as taken from the American Ephemeris, is given in this column.

Passing now to the right-hand page, the first column contains the number for reference.

Column *Circle Division* gives the degrees and minutes of circle reading as they would have been read by a fictitious horizontal microscope. From C may be deduced the four divisions of the circle on which the wires of the microscope micrometers were actually set; these divisions being,

		° ′
For microscope	V,	C + 314 34
For microscope	VI,	C + 44 34
For microscope	VII,	C + 134 34
For microscope	VIII,	C + 224 34

The circle division being usually copied into the observing-books from a table, or from the result of a calculation, it is to be regarded, at least in the case of well-known objects, as a result of calculation rather than of observation.

Next we have the readings of the micrometers of the four microscopes of the east pier. As it was always intended to set the circle so that these micrometers should read 10 revolutions and some small number of seconds, their entire revolutions are not generally recorded unless their reading falls without the limits of $9^r\ 20''$ and $10^r\ 20''$.

The next six columns give the readings of the zenith distance micrometer. The entire revolutions are deduced from the position of the double movable wires on the toothed scale in the focus of the telescope. The center of the field, as marked by the double fixed wires, corresponds to 30 revolutions. Columns 1, 2, 3, 4, and 5 give the thousandths of a revolution, as read from the micrometer-head for the different bisections of the object by the micrometer. The vertical wires at which the bisections were made may be inferred as follows:

For stars of more than 5° polar distance the columns 1–5 correspond to wires I, II, IV, VI, and VII.

For stars within 5° of the pole they refer to wires C_1–C_5.

Stars within 20° of the pole were generally bisected at the times of transits over the wires of sets B and D. These cases are indicated in the foot-notes, the words "bisections at sets B and D" indicating that the were made at B_1, B_3, D_1, D_3.

When the bisections were not made at the regular wires, a note will be found at the foot of the page stating at what wires, or at what minutes and seconds of clock-time the bisections were made.

The zenith point correction is derived entirely from the last column in the observations of the nadir point and collimators, the varying correction being interpolated between the times of its separate determination in such a way as to give its most probable value for each celestial observation. If the difference of consecutive determinations, or between three determinations on the same day, did not amount to half a second, the mean result was generally used throughout. When the difference exceeded this amount the varying series was made to approach each determination within an amount which increased with the discrepancy of the determinations.

The apparent zenith distance south is formed of the sum of the following quantities:

1. The mean circle reading formed by applying the mean of the excess of the microscope micrometer readings above 10 revolutions to the circle division.

2. The correction for mean reading of zenith distance micrometer. The value of this correction is,

$$R\ (M - 30^{r}) + 4'$$

R being the value in arc of one revolution of the micrometer, and M the mean micrometer reading. The constant 4′ is added to make the correction positive. This correction may be deduced from Table VI, of the volume for 1866, by subtracting the result from 7′.

3. The reduction to the meridian on account of deviation of the path of the star from a great circle. This correction depends upon the polar distance of the star and its hour-angle, or the vertical wire at which it was observed. It was taken from Table VIII,* in which the numbers are increased by 1″.80 to make them generally additive. When the bisections were made by clock-time, the correction was taken from the tables in the Appendix to the Washington Observations for 1845.

4. In case of unsymmetrical observations the corrections for inclination of wires and motion of object. The inclination was determined from time to time by comparing the micrometer readings of great numbers of stars at the first and last vertical wires. It was undisturbed and sensibly constant during the year. Its amount is given on page 3 of the Observations.

5. In the irregular cases in which wire A or B was used, the corrections for the distance of these wires from the middle pair. These corrections are found on page 3 of the Observations.

6. The zenith point correction in the preceding column.

At the beginning of 1867 the heads of the microscope micrometer screws were so adjusted that the mean correction for periodic inequalities of the screws should be very small. This correction was therefore not applied during the year 1869.

The corrections for flexure and division errors are not applied in the reductions, it being intended to apply them once for all to the concluded mean places of the stars and the apparent places of the planets.

The next column gives the reading of the sympiesometer. The readings of the external thermometer, barometer, and its attached thermometer, corresponding to occasional readings of the sympiesometer, and serving as a check upon it, are found at the foot of the page.

The refraction is computed from the apparent zenith distance, and the readings of the thermometers and barometer by means of the expansion of Bessel's Refraction Tables, found in the Appendix to the Washington Observations for 1845, using only four places of decimals. But generally the sum of the logarithms of the factors for barometer and external and attached thermometers are deduced at once from the reading of the sympiesometer by applying a small correction. This correction is given in the following table:

S.	Corrections.
400	+ 4
450	3
500	3
550	3
600	4
650	5
700	8
750	6
800	7
850	8
900	+ 9

The correction is deduced from comparisons of the sympiesometer readings with the results of the barometer and thermometer readings.

* Washington Observations for 1866, p. xxxiii.

The units of sympiesometer reading and correction both correspond to the fourth place of decimals in the logarithm of refraction.

When a star was too near the horizon to regard the refraction as a function of the height of the sympiesometer simply, the refraction was computed in the usual way. The apparent north polar distance is formed by adding the apparent zenith distance south, corrected for refraction, to the colatitude in case of a direct observation, or subtracting it in case of a reflection observation. The adopted colatitude is

$$51^\circ\ 6'\ 21''.2$$

The column *Miscellaneous Corrections* contains the following quantities:

α. In case of stars of the American Ephemeris, the apparent correction to the north polar distance there given.

β. In case of other stars the reduction of the apparent north polar distance to the mean north polar distance at the fictitious epoch 1870.0, using the constants of the American Ephemeris and omitting proper motion.

γ. In the case of planets other than the moon, the correction for parallax, in computing which the sun's mean equatorial horizontal parallax has been taken equal to

$$8''.85$$

In the case of the moon the corrections for parallax and semi-diameter will be found at the foot of the page. They are both computed from the data of the American Ephemeris, pages 341–344, the adopted formula for parallax being

$$\sin p' = [9.999430] \sin \pi \sin (\text{Z. D.} + \text{refraction} - 11'\ 14''.5)$$
$$p = p' \pm \delta p.$$

π being the interpolated value of the horizontal parallax, and δp the small correction taken from Table XI of the Appendix to the Washington Observations for 1865.

OBSERVATIONS OF THE NADIR POINT MADE TO DETERMINE THE ZENITH POINT CORRECTION OF THE TRANSIT CIRCLE.

The first column gives the mean day and tenth of a day, and the sidereal hour. The time of observation is thus, as a general rule, fixed within an hour. Failures on the part of the observer to record the exact hour are, however, very frequent.

The readings of the microscope micrometers are those taken from their heads when their wires are set on the following divisions:

	°	′
Microscope V,	134	30
Microscope VI,	224	30
Microscope VII,	314	30
Microscope VIII,	44	30

As already explained, the circle reading is referred to a fictitious horizontal microscope, which reads 179° 56′ when the telescope points to the nadir.

The entire revolutions of micrometer V are seldom recorded, unless they differ from 10. They may generally be inferred from the circumstance that the circle is usually set on or near 10 revolutions when a collimator was observed.

The next column shows the readings of the zenith distance micrometer for coincidence of each wire of its close pair with the image of the adjoining wire, or for coincidence of the mean wire with its image. A correction of $+0^r.250$ is to be applied to all these readings on account of a different index being read from that read in celestial observations.

The next column gives the concluded zenithal circle reading.

Lastly, we have the zenith point correction resulting from the observation. To obtain it, the circle reading should be corrected by the following quantities:

	$''$
Flexure of circle	+ 0.86
Effect of gravity on micrometer	— 0.30
Constant added to reduction to meridian in the reduction of celestial observations	+ 1.80
Total	+ 2.36

The circle reading thus corrected being subtracted from 360° will give the zenith point correction to be applied in the reductions. The correction actually used was, however, through some mistake, $2''.76$, so that the correction and the direct zenith and polar distances are all too small by $0''.40$, and the reflection distances too great by the same quantity. The error is eliminated by the correction for discordance of direct and reflection observations.

CORRECTIONS TO THE STAR POSITIONS OF THE AMERICAN EPHEMERIS, GIVEN BY INDIVIDUAL OBSERVATIONS OF STARS WITH THE TRANSIT CIRCLE. (Pages 238–247.)

Here are found (1) the date of each observation and (2) the initial of the observer. The latter is given to facilitate any discussion of personal peculiarities.

Next follows the correction to the right ascension. This is copied, without change, from the last column of the left-hand page of the observations. In the case of clock-stars, it is not put down unless it depends either on three other clock-stars, or on one or two stars distant more than six hours in right ascension.

In this and the following column a colon signifies that the result is doubtful; an *r* that it is rejected on account of discordance.

In the next column we have the correction to the polar distance, also copied from the last column of the observations, without change, except for erroneous micrometer revolutions.

The mean polar distances thus found still require the following corrections, which were not applied in the reductions:

1. For error of division.
2. For flexure.
3. For possible constant error in zenith point.
4. For error of assumed latitude.

The correction for error of division may be deduced from the table for circle B, given in § 72 of the description of the Transit Circle; the argument of the table being,

$$\left.\begin{array}{r} 38^\circ.4 - \text{Dec.} + i \times 90^\circ \\ \text{or } 38^\circ.4 + \text{N. P. D.} - i \times 90^\circ \end{array}\right\} \text{For direct observations.}$$

$$\left.\begin{array}{r} \text{and } 51^\circ.6 + \text{Dec.} - i \times 90^\circ \\ \text{or } 51^\circ.6 - \text{N. P. D.} + i \times 90^\circ \end{array}\right\} \text{For reflection observations.}$$

i being a whole number to bring the argument into the first quadrant. From this table, the correction for the nadir point, corresponding to 180° of the finding microscope, comes out $+ 0''.30$. As this correction has not been applied, it must be subtracted from all the division corrections. Moreover, to reflection results, the division must be applied with its sign changed. The final correction is given in one of the following tables.

The concluded correction for division is under the mean "Correction to the ephemeris" for each star. Under this again, in the line Flex., &c., is given the sum of all the other systematic corrections. As one of these corrections is derived from a comparison of the direct and reflection observations, the next step will be the discussion of that comparison.

COMPARISON OF DIRECT AND REFLECTION DETERMINATIONS OF POLAR DISTANCE.

This comparison is given in the following table. Column D. — R. gives the difference of results corrected only for error of division. The weights are not proportional to the number of observations, but are taken on the supposition that each star is affected with a probable constant error nearly one-third as great as the accidental errors of the individual observations. The formula actually employed is,

$$\text{Wt.} = \frac{12\,n}{n + 11}$$

Star.	Z. D.	D.	R.	Sine flex., etc.	D.−R.	Wt.

The number of observations is too small to deduce any law of variation on either side of the zenith. Taking the mean value of D. — R. for all the north stars, and then for all the south stars, we find

		$''$
Mean value of D.—R. north of the zenith	. .	— 0.54
Mean value of D.—R. south of the zenith	. .	— 0.90

or, correcting the results for error of zenith point correction just mentioned, they will be

		$''$
North	. .	+ 0.26
South	. .	— 0.10

This result is decidedly different from that of 1867, when the position of the instrument was almost exactly the same. It would seem, therefore, that the discordance depends on some cause which may vary from year to year. The most remarkable feature of the change is that the excess of reflection measures of north polar distance of stars south of the zenith is reduced from $1''.19$ to $0''.36$.

The corrections to be applied to different classes of observations will be determined, as in former years, on the supposition that the mean of the direct and reflection results is correct. The change of $0''.18$ near the zenith will be supposed to take place progressively from 355° to 5° zenith distance. The corrections to reduce the direct and reflection to one uniform system will then be:

		$''$
To direct results	. . . .	$+ 0.06 \sin Z + \alpha$
To reflection results	. . . . .	$+ 0.10 \sin Z - \alpha$

Where $\alpha = + 0''.27$ for zenith distances between 185° and 355°
$\alpha = + 0.45$ for zenith distances between 5° and 175°

To obtain absolute polar distances two more corrections are still necessary, one for cosine flexure of the telescope, and one for error in the assumed latitude.

The first can be obtained with most precision and certainty from a comparison of the zenith distances of the same stars found in opposite positions of the instrument. A comparison of the results for 1866 and 1867 indicated that the telescope tube itself, or, more precisely, the line joining the center of the object-glass and the fixed horizontal wires of the instrument, is not affected with any sensible cosine flexure. This result is probably very nearly correct, and, besides, its error, if any exist, will be eliminated from the mean of any two consecutive years' work with the instrument. Assuming its correctness, the cosine flexures to be actually applied will be those of the circle and the zenith distance micrometer. During the year 1867 the circle (B) was so set that it read 359° 30′ at the zenith, the readings increasing toward the south. The corrections to be applied to the zenith distances south, whether observed directly or by reflection, are*

Flexure of micrometer	. . . .	$+ 0.30 \cos Z$
Flexure of circle B	. . . .	$- 0.86 \cos Z$
Total	. . . .	$- 0.56 \cos Z$

INVESTIGATION OF THE CORRECTION TO THE ADOPTED LATITUDE, FROM THE OBSERVATIONS OF 1869.

The sum of all the corrections thus far found is applied to the mean north polar distances of each star observed on both sides of the pole in the course of the year. Its value is as follows:

		$''$ $''$ $''$
To direct results	. . . .	$+ 0.06 \sin Z - 0.56 \cos Z + 0.27 +$ Div.
To reflection results	. . .	$+ 0.10 \sin Z - 0.56 \cos Z - 0.27 -$ Div.

* Description of the Transit Circle, §§ 61, 67.

The resulting corrections to the positions of the American Ephemeris are given in columns 3 to 7 of the following table. The small subscript figures indicate the weights.

Star.	Dec.	Corrections.		$2\,\delta\,\phi$	$2\,W\,\delta\,\phi$
		U. C.	S. P.		
	°	"	"	"	"
Polaris	88	$+\,0.20_{11}$	$-\,0.06_{13}$	$+\,0.14_{12}$	$+\,1.68$
δ Ursæ Minoris	87	$-\,1.61_{3}$	$+\,0.49_{8}$	$-\,1.12_{2}$	$-\,2.24$
50 Cassiopeæ	72	$-\,0.75_{1}$	$+\,0.07_{2}$	$-\,0.68_{1}$	$-\,0.68$
β Cephei	70	$-\,1.42_{2}$	$+\,1.53_{2}$	$+\,0.11_{1}$	$+\,0.11$
ι Cassiopeæ	70	$-\,0.44_{1}$	$+\,0.41_{2}$	$-\,0.03_{1}$	$-\,0.03$
δ Draconis	67	$+\,0.45_{1}$	$+\,0.08_{1}$	$+\,0.53_{\frac{1}{2}}$	$+\,0.26$
α Camelopardi	66	$+\,0.28_{1}$	$-\,1.44_{1}$	$-\,1.16_{\frac{1}{2}}$	$-\,0.58$

The resulting correction to the assumed latitude is only $-\,0''.04$ instead of $-\,0''.50$, as in previous years. Comparing this with the change in the discordance of direct and reflection observations, it will be seen that the change is due mainly to the reflection observations.

It may therefore be of interest to inquire what value of the latitude would have been derived from direct and reflection observations separately in the different years in which the instrument has been in use. The zenith distances have been actually reduced on the following system:

(1.) In the preliminary reductions the zenith distances are reduced provisionally with a zenith point correction derived from nadir observations, or, during parts of 1866 and 1867, from observations of the leveled collimators.

(2.) The comparison of direct and reflection observations shows the correction which must be applied to the provisional zenith point correction to obtain the zenith point correction which would have been derived from the combination of direct and reflection observations. The correction thus obtained is applied to all the zenith distances of stars. It is also found that this correction is sensibly constant on each side of the zenith, but changes at or near that point by an amount varying between $0''.60$ in 1867, and $0''.18$ in 1869. When the zenith distances are thus corrected, the latitudes derived from direct and reflection observations are necessarily identical.

(3.) If we had depended solely on nadir observations for the zenith point, independent values of the latitude would have been derivable from the direct and from the reflection observations. But we should first have to know the exact value of the cosine flexure of the telescope, which we have not yet succeeded in determining otherwise than by comparison of different years' work in which the instrument was in opposite positions. The general result of this comparison is that the telescope-tube itself is not affected with any sensible cosine flexure, and that the latter depends solely on the micrometer and the circle. The correction actually applied has, however, never corresponded exactly with this hypothesis. We therefore give the derivation of the necessary correction to the provisional zenith distances, as follows:

	1866.	1867.	1868.	1869.
	"	"	"	"
Correction to nadir circle reading for flexure of circle	−0.01	+0.86	−0.86	+0.86
Correction of circle reading for effect of gravity on micrometer	+0.30	−0.30	+0.30	−0.30
Total correction	+0.29	+0.56	−0.56	+0.56
Correction actually used in provisional reductions	−0.14	+0.95	−0.86	+0.96
Difference to be subtracted from direct polar distances as provisionally reduced	+0.43	−0.39	+0.30	−0.40

We next apply these corrections to the mean value of $\frac{1}{2}$(D. − R.) derived from north stars, and thus find that the half value of the discordance would have been, if the proper zenith point correction had been used,

	"
1866	+ 0.53
1867	+ 0.84
1868	+ 0.48
1869	− 0.14

We now add this correction to the latitudes, given by the separate years' work, to get the result of direct observations, and subtract it to get the result of reflection observations. The result is:

Year.	Latitude deducible from—	
	Direct observations.	Reflection observ'ns.
	° ′ ″	° ′ ″
1866	38 53 38.73	38 53 37.67
1867	39.16	37.48
1868	38.69	37.73
1869	38.62	38.90

This result tends to throw suspicion on the reflection observations of zenith distance, and on the corrections to the latitude derived from them. The observations of polar distance having always been reduced to what they would have been if measured from a visible pole, any error of the latitude is eliminated from the concluded polar distances of all stars.

It may also be remarked that had the reflection observations been entirely rejected, there would have been no systematic differences between the polar distances of the northern stars then deduced and those actually concluded, while the actually concluded polar distances of southern stars would have been changed by the following amounts:

	″
1866	— 0.47
1867	— 0.60
1868	— 0.68
1869	— 0.18

By applying these corrections to the concluded N. P. D.'s of southern stars for the several years, they will be reduced to N. P. D.'s not differing *systematically* from those which would have been derived from direct observations alone.

Proceeding on the same system as in former years, we have the following corrections to be applied to the results of the preliminary reductions of the observations of 1869:

SYSTEMATIC CORRECTIONS TO BE APPLIED TO THE REDUCED NORTH POLAR DISTANCES OF OBJECTS OBSERVED DURING 1869, ON ACCOUNT OF DIVISION, FLEXURE, ERROR OF ASSUMED LATITUDE AND ZENITH POINT, AND DISCORDANCE OF DIRECT AND REFLECTION OBSERVATIONS.

POSITIONS OF THE SUN, MOON, AND PLANETS, DEDUCED FROM OBSERVATIONS WITH THE TRANSIT CIRCLE.

When both limbs of an object presenting a fully-illuminated disk were observed, the right ascension here given is that of the mean of the two limbs, as found in column *Apparent R. Ascension* of the observations.

When only one full limb was observed the right ascension of the center is found by applying the sidereal time of semi-diameter passing meridian, as given in the column *Miscellaneous Corrections*, without correction except for the sun. For this object, the semi-diameter corresponding to the observer, as given in the preceding volume, has been used.

When one of the limbs observed was defective, the observed difference of right ascension of limbs was multiplied by the computed ratio of this difference to the true semi-diameter, and the observed semi-diameter thus deduced was applied to the right ascension of the full limb to obtain that of the center. The adopted formulæ for the computation are as follows: Put

i = elongation of earth and sun as seen from planet.
$b = \cos i$.
δ, δ' = declinations of planet and sun.
A = difference of their right ascensions.
θ = angle which the line of cusps makes with the meridian.
f, f' = factors by which measured horizontal and vertical diameters must be multiplied to obtain true semi-diameter.

To find f we then have

$$\tan \theta = \frac{\cos \delta \tan \delta'}{\sin A} - \frac{\sin \delta}{\tan A}$$

When the planet is gibbous

$$g = \cos \theta \sqrt{b^2 + \tan^2 \theta} = \cos \theta'' \text{ when } \sin \theta'' = \cos \theta \sin i$$
$$g' = \sin \theta \sqrt{b^2 + \cot^2 \theta} = \cos \theta' \text{ when } \sin \theta' = \sin \theta \sin i$$
$$f = \frac{1}{1+g}$$
$$f' = \frac{1}{1+g'}$$

When the illuminated disk is a crescent,

$$g = \cos \theta; \qquad f = \frac{1}{1+g}$$
$$g' = \sin \theta; \qquad f' = \frac{1}{1+g'}$$

When the center of light of Mercury was observed, let ε be the reduction to true center. The value of ε was obtained from the empirical formulæ

$$n = \frac{(1-b)\ (5+b)}{12}$$

in R. A. ε = semi-diam. $\times\ n \cos \theta$
in N. P. D. ε = semi-diam. $\times\ n \sin \theta$

The north polar distances are reduced from the part actually observed to center in the same way with the right ascensions, and by the formulæ and numbers just given. The following further corrections are then applied:

1. The parallax in altitude found in the last column of the observations.
2. The corrections for division, flexure, latitude, and constant of zenith point, taken from the last column of the preceding table.

The columns of corrections always give, in the first place, the corrections to the positions given in the transit ephemeris of the American Ephemeris and Nautical Almanac. No transit ephemeris of the moon

being there found, the tabular right ascension is computed thus: the *observed right ascension of center*, considered as sidereal time, is reduced to Washington mean time, and the correction

$$5^h\ 8^m\ 12^s$$

applied to reduce it to Greenwich time. The co-ordinates are then interpolated to this moment from the Greenwich part of the Ephemeris.

When the polar distance only was observed, the mean time was taken immediately from the "Moon culminations" of the American Ephemeris.

The tabular place from Hansen's tables of the moon is interpolated from the British Nautical Almanac in the same way.

The observed positions of Venus and Mars are also compared with Le Verrier's tables. The co-ordinates are here interpolated occasionally from the British Nautical Almanac, as a check, but in most cases are obtained by applying to the transit position of the American Ephemeris the differences between the positions for Greenwich noon given in the two Ephemerides.

The positions of Neptune are also compared with Newcomb's tables, the tabular positions being interpolated from the Appendix to the American Ephemeris for 1869.

In the list of observed positions of the small planets, the Washington mean time is computed from the observed right ascension. This is increased by $6^h\ 1^m.8$ to reduce it to Berlin time, and the "aberration time," — [0.9148] $\varDelta$, usually given in the Ephemeris, is subtracted. Thus we have the Berlin mean time at which the light left the planet. To this time the position given in the Ephemeris is interpolated.

The Ephemeris with which each observed position of the asteroids is compared is indicated after its name, the following abbreviations being used:

B. Y.—Berliner Astronomisches Jahrbuch.
A. N.—Astronomische Nachrichten.

THE MERIDIAN TRANSIT INSTRUMENT.

During the year this instrument was used for observing stars whose positions in declination had been previously determined by the Mural Circle or the Prime Vertical Transit Instrument, and for a portion of the year the moon and the larger planets were likewise observed. The method of observation was that used in previous years.

The transit system consists of five groups or tallies of vertical threads, and in addition to these there are three vertical threads, movable by a micrometer-screw, and two stationary horizontal ones. With the clamp-end of the axis to the east, the tallies are named in the order of the transit of stars above the pole A, B, C, D, and E.

The tally over which an object has been observed is shown by the inspection of the intervals between the threads. The individual threads of each tally are designated by the numbers 1, 2, 3, 4, 5, for A, C, and E, and 1, 2, and 3 for B and D, respectively. One vertical thread, A_0, is outside of tally A, and another, E_6 is outside of E. These two, with A_5, B_1, C_3, E_3, and E_1, constitute a system over which transits with eye and ear may be conveniently observed.

From the mean of a number of observations of Polaris and δ Ursæ Minoris, the equatorial intervals between each thread and the mean of B_1, B_2, B_3, C_1. C_2, C_3, C_4, C_5, D_1, D_2, D_3, were found to be as follows, the notation corresponding to clamp east:

EQUATORIAL INTERVALS.

Thread.	Interval.	Thread.	Interval.	Thread.	Interval.	Thread.	Interval.	Thread.	Interval.
	s.		s.		s.		s.		s.
A_1	+35.628	.	. .	C_1	+2.197	D_1	−11.869	E_1	−30.231
A_2	+34.493	.	. .	C_2	+1.218	D_2	−12.950	E_2	−32.641
A_3	+33.084	B_1	+15.021	C_3	−0.003	D_3	−14.978	E_3	−33.888
A_4	+31.836	B_2	+12.966	C_4	−1.188	.	. .	E_4	−35.137
A_5	+29.762	B_3	+11.808	C_5	−2.222	.	. .	E_5	−36.365

On the 13th of October, the threads having been destroyed by an accident, a new set was put in by Mr. Gardner on the old scores nearly. The intervals of these threads read as follows:

Thread.	Interval.	Thread.	Interval.	Thread.	Interval.	Thread.	Interval.	Thread.	Interval.
	s.		s.		s.		s.		s.
A_1	+35.702	.	. .	C_1	+2.365	D_1	−11.901	E_1	−30.147
A_2	+34.583	.	. .	C_2	+1.257	D_2	−13.091	E_2	−32.605
A_3	+33.253	B_1	+14.715	C_3	+0.125	D_3	−14.715	E_3	−33.828
A_4	+31.951	B_2	+12.927	C_4	−1.167	.	. .	E_4	−35.017
A_5	+29.831	B_3	+11.785	C_5	−2.303	.	. .	E_5	−36.289

The intervals for A_0 and E_6, not having been used, are not given.

The times of transit of all objects more than 5° distant from the pole were recorded by means of the Morse register.

INSTRUMENTAL ERRORS.

Aided by a collimating eye-piece, the error of level and collimation were obtained by reversing the instrument over a basin of mercury, and measuring with the micrometer-screw of the eye-piece the distance between the central thread and its image seen in the mercury. If we represent by 2Δ the distance of the central thread west of its image when the clamp-end of the axis is east; by $2\Delta^1$, the same quantity, when the clamp is west; by p, the excess of the radius of the clamp-pivot divided by the distance between the pivots; and by $-r$ the reduction of the central thread to the mean of the system B_1, B_2, B_3, C_1, C_2, C_3, C_4, C_5, D_1, D_2, D_3, and by a the correction for diurnal *aberration* $= -0^s.016$ in this latitude, we have:

$$c = \tfrac{1}{2}(\Delta - \Delta^1) - p + r + a, \text{ for clamp east.}$$
$$c = -\tfrac{1}{2}(\Delta - \Delta^1) + p - r + a, \text{ for clamp west.}$$
$$b = -\tfrac{1}{2}(\Delta + \Delta^1) - p, \text{ for clamp east.}$$
$$b = -\tfrac{1}{2}(\Delta + \Delta^1) + p, \text{ for clamp west.}$$

The value of p, as determined in 1864, was $p = +0^s.008$; the numerical value of r for the current year is $r = 0^s.00$. After October 13 the value of r is $r = -0^s.125$. All the observations for determining the errors of collimation and their results are given in the subjoined table, in which r, the value of a revolution of the micrometer, is $1^s.5865$. When great changes occur in the values of c between consecutive dates, they have been caused by adjustment with the collimating screws.

	30	− 0.15	− 0.36	+0.063	−0.095		31	0.00	− 0.17	−0.081	+0.049

When observations to determine the value of c are tolerably accordant on successive dates, a mean is adopted for the whole period of such accordance; and where the differences are too great to permit inference that they may be due to errors of observation, the changes are assumed to have been uniformly progressive.

The values used in the reductions are stated at the bottom of each page of the printed observations.

The distance which the line of collimation passes from the pole and the point in which the meridian intercepts the equator are used instead of errors of level and azimuth. When the error of collimation is known, the first distance is directly obtained by observations of stars very near the pole, and may be represented by n. The second distance is determined by combining the value of n with the error of the level. Designating the latter by b, the latitude of the Observatory by φ, and representing this second distance by m, we obviously have,

$$m = -n \tan \varphi + b \sec \varphi$$

and the correction applicable to the observed transit of any star, to reduce it to the meridian, will be obtained by the formula,

$$\text{Correction} = m + n \tan \delta + c \sec \delta$$

in which δ represents the apparent declination of the star.

An approximate clock-error having been first obtained from one or more equatorial stars, the value of n was determined generally by comparing the time of transit of Polaris, δ Ursæ Minoris, λ Ursæ Minoris, or 51 Cephei, with the right ascension given in the American Ephemeris and Nautical Almanac for the year 1870, reduced to the date of the observation.

The value of n, found in this manner and used in the reduction of the stars, is published in the table at the bottom of the page of the published observations, under the head of corrections, &c.

It will be readily seen that if m is neither large nor subject to great variation, it will be eliminated through the clock-error. It has not been used separate from the clock-error except when the instrument was used for regulating the mean time of the Observatory, or when large enough to affect the reduction of the moon, and is therefore not always published in it susual place.

The clock-error was obtained from the corrected transits of one or more of the standard stars whose mean place for 1870.0 is given in the American Ephemeris.

The apparent place of these stars for the date was taken from the Ephemeris for 1869.

The clock used in observing was that of Charles Frodsham, and occasionally the Kessels clock.

EXPLANATION OF THE PRINTED OBSERVATIONS.

Column 1 contains the date and initial letter of the observer's name, the day commencing at apparent noon.

Column 2 contains the name of the object, or its approximate declination.

The following system of nomenclature was adopted. Stars contained in the Catalogue of the British Association are designated in the order of precedence:

1. By the constellation and Bayer letter there given.
2. By the constellation and Flamsteed number there given.
3. By their number in the catalogue.

Other stars found in published catalogues are designated by the name and number in the catalogue.

Column 3 contains the number for reference.

The following abbreviations occur:

O. Arg. N.—Oeltzen's Catalogue from Argelander's Northern Zones.

O. Arg. S.—Oeltzen's Catalogue from Argelander's Southern Zones.

Weisse (2) for Weisse's Catalogue from Bessel's Zones, from 15 to 25 degrees of north declination.

Some anonymous stars, used in the comparisons of the equatorial, are denominated by a number, followed by the letter W.

Columns 4 to 14, inclusive, contain the seconds and tenths of the transits over the several threads, as noted by the observer at the time, or as subsequently read from the chronographic record; but as there are twenty-one threads, over each of which observations were taken at different times, the numbers over the columns may not represent the thread at which a star was observed, and this can only become known by comparing the observation with the equatorial intervals.

Column 15 contains the minutes, seconds, and decimals of a second obtained by taking the mean of the preceding times of transits over the threads observed.

Column 16 contains the sum of the corrections necessary to reduce the numbers of the preceding column to the clock-time at which the object crossed the great circle passing through the pole, and the point in which the line of collimation intersects the equator. It consists of two parts:

1. For broken observations of stars, from the mean of the threads B_1, B_2, B_3, C_1, C_2, C_3, C_4, C_5, D_1, D_2, D_3, by the formula,

$$R = \text{equatorial interval} \times \sec \delta$$

or, if the star was so near the pole that the difference between the sine and arc of the reduction was sensible,

$$\sin R = \sin \text{equatorial interval} \times \sec \delta$$

In case of the moon, the reduction was computed by Professor Airy's formula, published in the Greenwich Observations—

$$\frac{3600 + I}{3600} \times \frac{\sin ☽\text{'s Geo. Z. D.}}{\sin ☽\text{'s App. Z. D.}} \sec ☽\text{'s Geo. Z. D.}$$

in which I represents, in seconds of time, the moon's increase of right ascension in one hour of longitude, as given in the Nautical Almanac.

2. The correction for collimation and polar azimuth computed by the formula,

$$\text{Correction} = n \tan \delta + c \sec \delta$$

of which the method of obtaining the factors n and c has already been stated.

Column 17 contains the correction for clock-errors, obtained as stated, and brought forward to the instant of observation by the rate.

Column 18 contains the apparent right ascension of the object observed, obtained from the sum of the three columns immediately preceding.

Column 19 contains the corrections applicable to the preceding column to reduce the observations of the stars to their mean places, 1870.0, or the instant when the sun's mean longitude was 280°. These were computed from "Constants for the reduction of fixed stars," given in this volume, and in the preparation of which the coefficients are the same as those used in the American Ephemeris and Nautical Almanac. The corrections include no proper motions except those used in the list of time and azimuth stars.

There will be found at the foot of the page the adopted clock and instrumental corrections, observations of the reflected image of the middle thread, position of the clamp E. or W., and such notes as the observations called for. The several observations of each fixed star reduced to its mean place for 1870.0 are collected in pages 249–291.

As a general rule, the results for the fundamental stars are not given when there were less than four observations in the group used for determining clock-errors.

The magnitude of each star, when estimated by the observer at the time of observation, is given in the tables.

The observations of the year with this instrument were made by Professors Yarnall and Eastman, and Messrs. Frisby and Bardwell, assistant observers. The observations were reduced by Professor Yarnall, and copied by Mr. Thomas Harrison, the clerk of the Observatory. The list of mean places was made out by Mr. Frisby, and the observations were checked by Professor Beecher.

THE MURAL CIRCLE.

During the year 1869 the Mural Circle was employed in observing stars whose right ascensions had been previously determined by the Transit Instrument, and for a portion of the year the moon and larger planets were also observed.

MICROMETER AND TRANSIT THREADS.

The diaphragm inserted in October, 1864, was in use throughout 1869. The intervals of the threads were as follows:

Thread . .	I.	II.	III.	IV.	1.	2.	3.	4.	5.	VI.	VII.	VIII.	IX.
	s.	s.	s.	s.	s.	s.	s.	s.	s.	s.	s.	s.	s.
Interval .	+ 53.6	+ 40.6	+ 28.8	+ 15.7	+3.3	+1.6	0.0	−1.7	−3.5	− 16.3	− 28.8	− 40.8	− 52.9

The value of the micrometer-screw used was determined from the following observations made in 1870; the readings being for intervals of five minutes of arc:

	r.	r.	r.
March 22,	21.7081	31.3027	40.8596
April 18,	20.3742	29.9793	39.5384
May 4,	20.4879	30.0818	39.6453
May 6,	20.4637	30.0667	39.6156

These observations being reduced, give the value of r at 30 revolutions $r = 31''.316$.

From this value tables were made in which the variable value from the nadir to each extreme reading was considered as uniform and allowed for as such.

The following notes, bearing on the adjustment, &c., of the instrument, have been extracted from the observing-books:

March 18. Adjusted the inclination.
March 19. Re-adjusted micrometers C and D.
March 22. Found that the eye-piece had received a very hard blow.
March 27. Level found correct; adjusted collimation.
May 12. Adjusted microscopes to read alike.
June 12. Night's work rejected.

THE NADIR POINT.

For determination of the nadir point a cap is provided which fits loosely over any of the eye-pieces of the telescope. Just above the eye-lens the cap has a plate of thin glass inclined at an angle of 45°. This arrangement has the advantage of enabling the observer to collimate without removing the eye-piece used in observation, and thereby avoids the risk of injury to the threads, and prevents the frequent admission of dust by air-currents, &c.

The mode of observation is as follows: The circle telescope is so pointed that when the nadir divisions of the former are accurately under the zeros of the microscopes, the images of the horizontal threads in the field of the latter may be seen at a small distance from the threads themselves. The circle microscopes are read then or at the conclusion of the reflection measures.

The micrometer reading for the true nadir being that which corresponds to the coincidence of each thread seen directly, with the image of the other seen by reflection, the images were alternately made to measure, on each side of the threads, spaces equal to their distance apart. As the nadir point thus determined always depends upon the same set of divisions of the circle, and is made with the same part of the micrometer-screw, it is uniformly affected with the errors of those divisions and by an inaccuracy peculiar to that portion of the screw.

METHOD OF OBSERVING.

The method of observing was the same as in previous years, and consisted essentially in transferring the subdivision of the circle from the microscopes to the micrometer eye-piece. The circle was set so that the divisions nearest to the reading for the given declination were as accurately as possible under the zero of the microscopes. The circle microscopes were read either before or after the observation.

The observations of Mr. Doolittle were made by bisecting the objects with the southern horizontal thread, while Mr. Frisby and Mr. Bardwell observed them at an equal distance from each of the horizontal threads. For bisection observations the nadir reading was corrected by the quantity $-0^{r}.120$, the estimated half distance of the horizontal threads, made from a great number of observations.

EXPLANATION OF THE PRINTED OBSERVATIONS.

Columns 1 to 3 and 7 to 12 need no explanation beyond that given in former years. The magnitudes in column 4 are those estimated by the observer at the time of observation.

Columns 5 and 6 show the number of micrometer readings, generally three for each star, and the transit threads over which these readings were made. When the number of micrometer readings does not correspond to the number of threads included between the limits given in column 6, it is understood that the observations were made at equal intervals between those limits.

Column 13 contains the mean of the six microscope readings.

Column 14 contains the mean of the observed micrometer readings.

Column 15 contains the adopted "nadir correction," expressed in micrometer revolutions. It is formed by subtracting the excess of the micrometer reading above 30 revolutions from the excess of the mean circle reading above 100°, the reading of microscope A when the telescope pointed to the nadir, that excess being first expressed in micrometer revolutions.

Column 16 gives the corrected meridian micrometer reading formed by applying the following corrections to column 14:

1. The nadir correction.
2. The reduction to the meridian. For observations made on any of the vertical wires, the reduction is given by the formula,

$$\Delta\, m = -\frac{\sin^2 \frac{1}{2}\, h}{2\, r \sin 1''} \tan \delta$$

h being the equatorial interval in arc of the vertical wire, and r the value of one revolution of the micrometer. Expressing h in seconds of time, and putting for r its value, already given, this expression becomes

$$\Delta\, m = -\, [5.2405]\, h^2 \tan \delta$$

the value of which, for different wires, is tabulated on pages xxxii and xxxiii of the Introduction to the Washington Observations for 1863.

For stars near the pole, the time having been recorded, this expression becomes

$$\Delta\, m = -\frac{225 \sin 1''}{4\, r}\,(t - a)^2 \sin 2\,\delta$$

t being the true sidereal time of observations and a the right ascension of the star.

3. The correction of unsymmetrical observations of the sun, moon, and planets, on account of motion in declination. In the case of the moon the correction was computed by the formula,

$$\Delta\, m = [4.943]\; hs \sec \delta\, \Delta\, \delta;$$

hs being the equatorial interval in seconds of time of the vertical wire at which the observation is made, and $\Delta\delta$ the change of declination in seconds of arc for one hour of terrestrial longitude.

4. The correction of unsymmetrical observations for inclination of the micrometer-threads to the horizon. This was,

Jan. 1 to Mar. 19	. . .	$i = -0.17h$
Mar. 27 to July 6	. . .	$i = +0.30h$
July 6 to Dec. 31	. . .	$i = +0.41h$

i denoting the correction for inclination in thousandths of a micrometer revolution, and h the equatorial interval in seconds of time.

Columns 18, 19, and 20 contain the reading of the Newman barometer, its attached thermometer, and the external thermometer. The external thermometer is designated No. 3 in the Appendix to the Washington Observations for 1845, page 54. It is placed outside of the north aperture, several inches beyond the wall, and is read by the help of a sextant telescope attached to the window frame.

Column 21, entitled "Instrumental corrections," contains the micrometer equivalent, or the difference between the corrected micrometer reading and 30 revolutions converted into arc. If the former quantity is denoted by m, the values in this column will be given by the formula,

$$\text{Corr.} = (30 \text{ rev.} - m)\, r$$

Column 22 contains the apparent zenith distance, equal to the sum of columns 13 and 21, diminished by 90° if the sum be greater than 90°, or substracted from 90° if less. In the former case the result is marked S, as south; in the latter N, as north.

Column 23 contains the correction for refraction corresponding to the apparent zenith distance and the barometer and thermometer readings. This quantity is computed from Bessel's tables, as given in an expanded form in the Appendix to the Washington Observations for 1845. This correction, added to the apparent zenith distance, gives the corrected geocentric zenth distance, which is not printed.

The following corrections are applied to the thermometer readings for irregularities in the bore of the tube:

CORRECTIONS OF THERMOMETER.

64	+0.12	−.00010	100	−0.12	+.00010

2. The correction for parallax for observations of the sun, moon, and planets, computed for the first and last, by the formula,

$$p = \pi . \sin (z' - 11'.2)$$

For the moon:

$$\sin p' = \sin \pi . \sin (z' - 11'\ 14''.54) . [9.9994302,]$$

or

$$p' = \pi . \sin (z' - 11'\ 14''.54) . [9.9994302] \cdot \frac{\sin \pi}{\text{arc } \pi} \cdot \frac{\text{arc } p'}{\sin p'}$$

$$\text{and } p = p' \mp \tfrac{1}{2} (p \mp s) \sin p \sin s$$

the upper signs corresponding to observations of the upper limb, and *vice versa*. The quantities $\frac{\sin \pi}{\text{arc } \pi}$ and $\frac{\text{arc } p}{\sin p}$ are given in Tables IX and X, and the correction of p' in the last formula is given in Table XI of the Appendix to the Washington Observations for 1845.

In these formulas

z' represents the observed zenith distance, corrected for refraction.

π, the equatorial horizontal parallax, as given in the American Ephemeris.

s, the semi-diameter of the object.

p, the required correction for parallax.

3. In cases when only one limb of an object is observed, the correction for semi-diameter is included under this head. This correction is in all cases taken from the American Ephemeris.

Column 24 contains the declination of the star, using the assumed north latitude, 38° 53′ 39″.25.

Column 25 contains the reduction from the apparent declination at date to the mean declination for 1870.0.

It was computed by Bessel's formulæ, with constants prepared from the logarithms A, B, C, and D of the American Ephemeris and Nautical Almanac; and, in addition to the terms included in that work, it includes also those depending on twice the Moon's longitude. Corrections for proper motion have not been applied to any star.

Column 25 contains the initials of the observers' names:

D.—Mr. M. H. Doolittle.

F.—Mr. Edgar Frisby.

B.—Mr. F. W. Bardwell.

The observations were reduced by Professor Yarnall, and Mr. A. N. Skinner, assistant observer.

THE EQUATORIAL.

During the early part of the year 1869 this instrument was employed chiefly in observing stars in the group Præsepe. The results of these observations have been published in Appendix IV of the annual volume of the Naval Observatory for 1867. From May, 1869, until the latter part of October, the observer was absent in connection with the eclipse expeditions of that year.

The observations of Felicitas, (109), and the observed occultations of stars by the moon, will be found on pages 235 and 236. The observations of the planet were made in the same manner, and are printed in the same form as the Equatorial observations of 1868. Thus, $\Delta\alpha$ and $\Delta\delta$ are the observed differences of right ascension and declination; $\Delta\rho$ is the differential refraction; and α and δ are the apparent right ascensions and declinations uncorrected for parallax. Under the head $l.\ \Delta\ p$ are given the logarithms of the parallactic coefficients. The observations were made with the filar micrometer, and a magnifying power of 132 was employed. The value of one revolution of the micrometer-screw was assumed to be $15''.337$.

OBSERVATIONS

WITH THE

TRANSIT CIRCLE.

1869.

SUMMARY OF THE PRINCIPAL DATA FOR REDUCTION OF THE OBSERVATIONS MADE WITH THE TRANSIT CIRCLE DURING THE YEAR 1869.

Approximate distances of wires I to VII			$12\frac{1}{4}s.$
One revolution of the microscope micrometers			30″
One revolution of the telescope micrometer			$15.''320+0.''0068\ (r.-30r.)$
			′ ″
Correction for wire A	At vertical wire I		− 2 33.44
	At vertical wire VII		− 2 34.66
			′ ″
Correction for wire B	At vertical wire I		+ 2 30.90
	At vertical wire VII		+ 2 26.90
			″
Constant	Added to reduction to meridian	Subtracted from zenith point correction	1.80
			″
Corrections for inclination of wires	At vertical wire I		+ 1.00
	At vertical wire II		+ 0.66
	At vertical wire VI		− 0.66
	At vertical wire VII		− 1.00
			° ′ ″
Adopted latitude of the instrument			38 53 38.80
			s.
One division of hanging level			0.058
			″
One division of collimator levels			0.84

Position of the instrument. Clamp west.

Circle B, on the east end of the axis, was this year used in observation.

In reversing the instrument, the notation of the transit wires is also reversed, so that the wire which an equatorial star first reaches is always called wire I.

1.4–9.13–16.18.19. R. A. observed over wires I–VII.
2. R. A. observed over wires II, B, and D.
21. Wire B used.
23. R. A. observed over wire B_3 and sets C and D.
30. Bisections at set D.
33. Counting clock supposed to be 1^s wrong.
39.40. Five revolutions subtracted from reading of telescope micrometer.
43. R. A. observed over wires D_3 and VI. Bisection at wire VI.
44. Circle reading changed from 2° 4′ to 1° 56′, the 4′ being probably read the wrong way.

10. Wire B used.
21.37.38. Bisections at sets B and D.
25. Bisections at wires II–VI.
31.34.39.40. Wire A used.
41. Put level on pivots before reading microscopes.
44. After this observation adjusted focus of microscope V, pushing it in ¼ turn of screw.
46. Bisections at wires B_1, C_1, C_5, and D_3.

3. R. A. observed over wires B_2–D_2.
6. Seems five revs. wrong in N. P. D.
7. Telescope micrometer revolutions doubtful; probably 20.722 reduced on that supposition.
8. Bisections at wires B_1, C_1, C_5, and D_3.
10.11. Counting clock probably 1^s wrong.
11.30.41. Wire B used.
14. Bisection at D_3.
15. R. A. observed over C_1 and set B.
32. R. A. and bisection observed over wire I.
41. Revolution of telescope micrometer doubtful; reduced of the supposition 28.
42. Wire A used.

8. Revolution doubtful; probably 19. January 30 and 31. Setting microscope 2′ wrong.
20.39. Bisections at set B and D.
38. Bisections at VI½ and VII.
42. Probably one rev. wrong in N. P. D.
46. After this observation caught micrometer head with coat sleeve.
48. Probably five revs. wrong in N. P. D.

5. N. P. D. seems wrong.
20. Wire A used; observed for Leto.
25. Eye-piece taken out to adjust the self-adjusting levers.
38. R. A. observed over D, VI, and VII; last bisection 12ˢ after passing wire VII.
50. Bisections at sets B and D.

November 15, 10ʰ. Image west 0ʳ.06. Clamp east.
Image east 0ʳ.05. Clamp west.

Finding the movable wires impinged on the fixed ones, the plate was taken out, and a new wire (C_5) inserted in place of one broken out in removing the plate, and the systems were replaced somewhat farther separated, to prevent the movable wires from deranging the fixed ones.

November 16, 15ʰ. Image west 0ʳ.12. Clamp west.
Image east 0ʳ.05. Clamp east.

CONSTANTS FOR THE REDUCTION OF FIXED STARS.

These constants have been prepared from the Logarithms A, B, C, and D of the American Ephemeris and Nautical Almanac for the year 1869. The epoch to which the observations are reduced by them is 1870.0. The instant, 1870.0, is assumed to be January 0*d*.165, mean time, Washington, the moment when the Sun's mean longitude was 280°. The notation and form of publication is similar to that published in Volume III of the Washington Observations, and the auxiliary tables used in the eductions are similar to those of that volume.

CONSTANTS FOR THE REDUCTION OF FIXED STARS.

EPOCH MEAN MIDNIGHT, WASHINGTON.

METEOROLOGICAL OBSERVATIONS

MADE AT THE

U. S. NAVAL OBSERVATORY

DURING THE

YEAR 1869.

INTRODUCTION.

The meteorological department, during 1869, was under the charge of Professor J. R. Eastman, U. S. N., who made a daily examination of all the records and a weekly inspection of the instruments in use. In addition to his duties in the astronomical department, this officer performed all the work necessary to prepare the observations for the press. The observations were made at 0^h, 3^h, 6^h, 9^h, 12^h, 15^h, 18^h, and 21^h, Washington civil time, by the Observatory watchmen, Messrs. T. Hays, D. Horrigan, and N. Cahill, who have acquired such a degree of skill as insures reasonable accuracy in their work.

METEOROLOGICAL INSTRUMENTS.

Standard Barometer.—This barometer was made by James Green, of New York, and is used simply as a standard by which the Newman barometer is occasionally tested. Drawings and a description of this instrument will be found in the Annual Report for 1862.

Newman Barometer.—The barometer in daily use was made by Newman, and is mounted against the northern wall of the northwest room on the first floor of the Observatory. The cistern is 103 feet above the mean half-tide of the Potomac River. The cistern and tube are of glass; the internal diameter of the former being 3.0 inches, and of the latter 0.532 inch. The barometer is mounted with the usual adjustments at the top and bottom, and is attached by heavy brackets to a substantial mahogany board, which is firmly attached to the wall. The scale is attached to a brass rod, which has the usual adjustment to the surface of the mercury in the cistern. It is silvered and divided to 0.05 inch, but by means of a vernier may be read to 0.002 inch. The temperature of the mercury in the cistern is determined by a small ivory-scale thermometer, the bulb of which is constantly immersed in the mercury. The constant correction of +0.005 inch, which was determined in 1864, has been applied to all the observations in 1869, and they have also received a further correction for temperature.

Dry-Bulb Thermometer.—This is a mercurial thermometer by Green, with a bulb 1.5 inches long and 0.2 inch in diameter. It has a glass scale 12 inches long, 0.8 inch wide, and 0.1 inch thick. The divisions on the scale are engraved to half-degrees from $-30°$ to $+125°$ F. Several independent tests, in the early part of 1868, indicated that the *freezing-point* had changed its position on the scale since 1863. The following table of corrections was therefore deduced, and has been used in the reductions for this volume:

CORRECTIONS TO READINGS OF THE DRY-BULB THERMOMETER.

Scale Reading.	Correction.	Scale Reading.	Correction.	Scale Reading.	Correction.	Scale Reading.	Correction.
°	°	°	°	°	°	°	°
23	— 1.1	43	— 1.2	63	— 0.8	83	— 0.8

38	— 0.8	58	— 0.8	78	— 0.7	98	— 0.6
39	— 0.7	59	— 0.8	79	— 0.3	99	— 0.7
40	— 0.7	60	— 0.8	80	— 0.8	100	— 0.7
41	— 0.9	61	— 0.8	81	— 0.8		
42	— 1.1	62	— 0.8	82	— 0.8		

Wet-Bulb Thermometer.—This instrument is similar to the preceding in materials, construction, and dimensions. The scale extends from $-35°$ to $+115$ F°. Its bulb is covered with soft fine linen, which is kept moist by the capillary action of a bundle of fine linen fibers that communicate with water in a bird-glass placed close beside it. The linen is changed occasionally, before its free action is impaired by dust.

Maximum Thermometer.—This is a mercurial thermometer, with a bulb 1.5 inches long and 0.2 inch in diameter. The scale is of glass, 12 inches long, 0.8 inch wide, 0.1 inch thick, and is graduated to half-degrees from $-50°$ to $+120°$ F. A short distance above the bulb the internal diameter of the tube is so contracted that, while with the increase of temperature the mercury passes this point freely, with the least decrease of temperature the column is broken at the contracted point if the instrument is nearly horizontal, and the top of the column marks the highest temperature. The top of the scale is attached by a metallic clamp to a pivot, around which the instrument revolves freely in a vertical plane. This pivot is secured to a walnut board fixed to a post about three feet from the ground, and the thermometer is placed nearly horizontal by resting the scale near the bulb on a wooden pin in the board. After each observation the instrument is adjusted by removing the pin and allowing the thermometer to swing freely from the pivot at the top of the scale, which motion is sufficient to reunite the column of mercury.

Minimum Thermometer.—This is a transparent spirit-thermometer, with a round bulb about 0.5 inch in diameter. The scale is of silvered brass, 12 inches long, 1.0 inch wide, 0.06 inch thick, and is graduated to degrees from $-67°$ to $+131°$ F. Its registering index is a short, fine steel wire, inclosed in a delicate, blue glass cylinder, with a knob at the extremity furthest from the bulb of the thermometer. This cylinder is drawn toward the bulb by the decrease of temperature, but when the temperature increases the spirit flows through and around the cylinder, which remains at the lowest point reached by the spirit. After each observation the index is adjusted by means of a small magnet.

Solar Thermometer.—The mercurial solar thermometer was made by Green, and consists of a blackened spherical bulb and its tube inclosed within a bulb and cylinder of glass of the same form as the thermometer, but of about three times the diameter. Air has been exhausted from the cylinder, in the center of which the thermometer tube is fixed by cork collars, one being near each extremity. The scale is engraved on the thermometer tube, and has a range from $+5°$ to $+173°$ F. The temperature is registered in the same way as in the maximum thermometer, and after each observation the instrument is adjusted by holding it in a vertical position and gently tapping the external bulb. This thermometer rests in metallic crutches about three inches high, which are attached to a board 16 inches long and 5 inches wide. The board is painted green and placed on the grass about three yards west of the Meteorological Observatory.

METEOROLOGICAL OBSERVATORY.

In 1862 a small building for the special protection of thermometers was erected about four yards southwest of the southwest corner of the south wing of the Observatory. It is constructed of wood, and is painted white throughout. It is octagonal in form, each side being 2.4 feet wide by 6.3 feet high to the eaves. The roof is of tin, left bright on the under side. The ceiling is of thick plank, dovetailed together, and between it and the roof there is an open space communicating freely with the open air. The door is on the north side, and it, as well as the sides, is of double louver-work, with a space of three inches between the two divisions. The sides terminate one foot from the ground, and, as the building is situated on a grass-plat, under favorable circumstances the instruments should indicate correct temperature. The increasing density of the shade-trees and shrubbery in the Observatory grounds, and especially about this building, will, however, soon render some new arrangement absolutely necessary.

The dry and wet-bulb, and the maximum and minimum thermometers are within the Meteorological Observatory, and are all supported by means of arms and brackets to an upright metallic shaft, which is firmly secured to the ground in the center of the building.

The bulb of the minimum thermometer is 5.8 feet above the ground, those of the dry and wet-bulb thermometers are 4.2 feet, and that of the maximum is 3.2 feet above the ground.

A standard thermometer (Troughton and Simms, No. 1) is suspended between the dry and the wet-bulb thermometers, and is frequently read as a check on the others.

A wooden frame is attached to the sides of the building from which the self-registering thermometers which are issued to naval vessels with chronometers, are suspended for convenience in determining their errors by comparison with the standard.

From frequent comparisons it has been ascertained that the errors of the maximum, minimum, and wet-bulb thermometers are not appreciable, and the published observations are therefore the unmodified copies of the original record.

DIRECTION AND FORCE OF THE WIND.

An ordinary wind-vane revolves freely on a spindle at the top of the time-ball staff, and the direction of the wind is estimated from the known azimuths of the lines of the building.

The velocity of the wind is stated in numerals, of which 0 denotes a calm, 1 a very slight wind, and so on up to 10, which would indicate a violent hurricane. These numbers are mere estimates, and, at best are only approximative.

CLOUDS.

In the description of the prevailing forms of clouds the nomenclature of Howard is used; C., K., S., N., being the symbols for the forms which he designates *cirrus*, *cumulus*, *stratus*, *nimbus*; and the letters C. S., C. K., their combinations, indicate, *cirro-stratus*, *cirro-cumulus*, &c. The portion of the sky obscured is determined by estimate after careful scrutiny of the clouds or sky. A clear sky is denoted by 0, and a total obscuration by 10.

RAIN-GAUGE.

This instrument is placed within the inclosure for the protection of the solar thermometer. It consists of a cylinder 4.1 inches in diameter, soldered to an inverted cone, which is loaded with lead on the outside and near the apex. The cone rests in an apperture of a box, with a horizontal top, and this, aided by the weight of the lead, prevents disturbance during violent winds. The top of the gauge is 2.0 feet from the ground, and is free from all shelter even during driving rains. At the apex of the cone is a small apperture, through which the rain-water passes to a receiving bottle within the box, and is measured in a graduated glass cylinder with an internal diameter of 0.60 inch. It was examined at least once each day, and, as the apex of the cone closes the mouth of the bottle except through the small aperture, there is little or no loss by evaporation. Each inch of snow has been assumed equivalent to 0.111 inch of rain; but whenever practicable, the snow has been melted and the water measured in the gauge.

REMARKS.

July 8. Maximum thermometer fails to indicate the maximum reading.
9. Heavy rain, accompanied with lightning and thunder, at $0^h\ 45^m$ p. m. Amount of rain, 0.678 inch.
13. Showers, with lightning and thunder, at $2^h\ 20^m$ and $6^h\ 15^m$ p. m. Amount, 0.248 inch.
14. Showers, with much lightning and thunder, at $0^h\ 15^m$ a. m. and $7^h\ 20^m$ p. m. Amount, 0.020 inch.
15. A light shower, with vivid lightning, the latter continuing through the morning.
16. Lightning during the night. Several meteors; some very brilliant ones.
17. Showers at 3^h and $8^h\ 10^m$ p. m. Heavy thunder. Amount of rain, 0.320 inch.
18. Several showers after 7^h p. m. Frequent lightning and thunder. Amount of rain, 0.108 inch.
19. Rain at $9^h\ 30^m$ p. m., and continued through the night. Amount, 0.118 inch.

REMARKS.

August 21. Lightning and thunder at $6^h\ 20^m$ p. m. Lightning continued until midnight.

23. A light rain at noon.

24. Several meteors were seen during the evening. At $7^h\ 17^m$ p. m. a very bright meteor passed from near Mizar to a point 10° below Polaris, leaving a brilliant train, which remained visible five minutes.

28. A heavy shower at $7^h\ 45^m$ p. m. Amount, 0.606 inch.

29. Light shower at $2^h\ 40^m$ p. m. Amount, 0.030 inch.

30. Light showers at intervals during the morning.

REMARKS.

November 1. Light rain and hail at 1^h p. m. Amount, 0.004 inch.
2. Glass "jacket" of sun thermometer broken this afternoon.
5. Light rain at 6^h a. m.
7. A few snow-flakes at intervals during the day.
10. A brilliant meteor in the northwest at 6^h 53^m. Time of flight, 4 seconds.

LIST

OF

PUBLICATIONS PRESENTED TO THE LIBRARY

DURING

THE YEAR 1869.

LIST OF PUBLICATIONS PRESENTED TO THE LIBRARY IN 1869.

Date.	Publications.	From whom received.
Jan. 7	Mittheilungen der kaiserlich-königlichen geographischen Gesellschaft in Wien. Neue Folge. 1868.	A. Becker, General Secretary, Vienna.
	Jahrbücher der kaiserlich-königlichen Central-Anstalt für Meteorologie. Neue Folge. Band III. Jahrgang 1866.	Dr. C. Jelinek and C. Fritsch, Vienna.
	Planet Observationer anställda År 1867, på Lund's Observatorium.	Dr. Axel Möller, Director of the Observatory, Lund, Sweden.
	Bestämning af Polhojden för Lund's Observatorium medelst Observationer i första Vertikalen. Backlund.	A. V. Backlund, Lund, Sweden.
	Mittheilungen aus Justus Perthes' geographischer Anstalt, No. X, 1868, und Ergänzungsheft, No. 24.	Justus Perthes, Gotha, Germany.
	Die Temperatur-Abnahme mit der Höhe als eine Function der Windesrichtung. Hahn.	Dr. Julius Hahn, Vienna.
	Zu der Charakteristik der Winde des adriatischen Meeres	The same.
	Die thermischen Verhältnisse der Luftströmungen auf dem Obir (6288 pariser Fuss) in Kärnthen.	The same.
	Zeitschrift der österreichischen Gesellschaft für Meteorologie. Redigirt von C. Jelinek und J. Hahn. Band III, Nos. 16–20.	Dr. C. Jelinek, Vienna.
	Observations météorologiques faites à l'observatoire d'Upsal pendant les années 1855–'62.	Dr. Gus. Svanberg, Director, Upsala, Sweden.
	Om Stormen den 30 Maj 1865, och följan de dagar. R. Rubenson.	R. Rubenson, Upsala, Sweden.
	Astronomische Beobachtungen auf der Sternwarte zu Bonn. Von Dr. F. W. A. Argelander. 6ter Band, und 7ter Band, 1ste Abtheilung.	Dr. F. W. A. Argelander, Bonn, Germany.
	Abhandlungen der königlichen Akademie der Wissenschaften zu Berlin, 1861–'66.	Dr. A. Auwers, Secretary of the Imperial Academy, Vienna.
18	Publiche date del magnetoelettrico ed elettromagnetico dell A. B. Fran. Cav. Zantedeschi, 1868.	Francesco Cav. Zantedeschi, Padua.
	Monthly Meteorological Register at the Provincial Magnetic Observatory, Toronto, Canada West. April to December, 1867.	G. T. Kingston, Director of the Provincial Magnetic Observatory, Canada West.
	General Meteorological Register, 1867	The same.
	Astronomical, Magnetic, and Meteorological Observations made at the Royal Observatory, Greenwich, during 1866.	G. B. Airy, Esq., F. R. A. S., Astronomer-Royal, Greenwich.
	Results of Astronomical Observations, 1866	The same.
	Results of Magnetic and Meteorological Observations, 1866	The same.
20	La scienza alla exposizione universale di Parigi nel 1867. Osservazioni del Prof. Cav. F. Zantedeschi.	Prof. Cav. Francesco Zantedeschi, Padua.
	Beobachtungen an der kaiserlich-königlichen Central-Anstalt für Meteorologie und Erdmagnetismus, November, 1868.	Dr. C. Jelinek, Director Central-Anstalt, Vienna.
	Telegraphische Witterungsberichte, December, 1868	The same.
30	Journal of the Statistical Society of London, December, 1868	F. Purdy, Esq., Editor, London.
	Bulletin mensuel de la société zoologique impériale d'acclimatation.	M. Eugène Grisard, Agent, Paris.
Feb. 4	Le stelle cadenti del periodo di Agosto, osservate in Piemonte ed in altra de contrade d'Italia, nel 1868. Memoria IV del P. Francesco Denza, direttore dell osservatorio Reale Collegio Carlo Alberto in Moncalieri.	Padre Francesco Denza, Director of the Observatory, Moncalieri, Italy.
	Report of the Commissioner of Agriculture for the year 1867	Hon. Horace Capron, Commissioner.
10	Bulletin de la société de géographie. Octobre 1868	C. Maunoir, Secretary, Paris.
	Zeitschrift der österreichischen Gesellschaft für Meteorologie. Nos. 21, 22.	Dr. C. Jelinek, Vienna.
	Bericht der königlichen Sternwarte zu Berlin für das Jahr 1867	Dr. W. Foerster, Director of the Royal Observatory, Berlin.
16	Meteorological Observations made at the private observatory of J. Tebbut, jr., Windsor, New South Wales. 1863–'66.	John Tebbut, jr., Windsor, New South Wales.
18	A Synopsis of all Sir William Herschel's Micrometrical Measurements and Estimated Positions and Distances of the Double Stars described by him. Sir J. F. W. Herschel.	Sir John F. W. Herschel, London.
	Magnetische und meteorologische Beobachtungen zu Prag. 1860: 1865–'68.	Dr. Karl Hornstein, Director of the Observatory at Prague.
	Jahresberichte nam 24. Mai 1867 und 24. Mai 1868 dem Comité der Nicolai-Hauptsternwarte.	Otto von Struve, Director of the Pulkova Observatory.
	Note sur les satellites d'Uranus. O. Struve	The same.
	Bemerkungen über die gegen Herrn Le Verrier erhobenen Angriffe in Betreff der Identität des Neptun mit dem Planeten dessen Ort er aus den Uranus-Störungen theoretisch abgeleitet hatte. Struve.	Otto von Struve, Director of the Pulkova Observatory.
	Untersuchungen über die Constitution der Atmosphäre und die Strahlenbrechung in derselben. Dr. H. Gylden.	The same.

Date.	Publications.	From whom received.
Feb. 18	Nouvelle détermination de la parallaxe annuelle des étoiles α Lyræ et 61 Cygni. O. Struve.	Otto von Struve, Director of the Pulkova Observatory.
	Ueber Prof. Mädler's Untersuchungen über die eigenen Bewegungen der Fixsterne. Von C. A. F. Peters.	The same.
	Von den kleinen Ablenkungen der Lothlinie und des Niveaus welche durch die Anziehungen der Sonne, des Mondes und einiger terrestrischen Gegenstände hervorgebracht werden. C. A. F. Peters.	The same.
	Die Zeitbestimmung vermittelst des tragbaren Durchgangsinstruments im Verticale des Polarsterns. Struve.	The same.
	Die periodischen Erscheinungen des Pflanzenlebens. Linseer.....	The same.
	Observations de quelques étoiles doubles nouvellement découvertes. O. Struve.	The same.
	Résultats de quelques observations supplémentaires faites sur des étoiles doubles artificielles. O. Struve.	The same.
	Observations et orbite de l'étoile double Σ. 1728=42 Comæ Berenicis. O. Struve.	The same.
	Tabulæ auxiliares ad transitus per planum verticale reducendos inservientes. O. Struve.	The same.
	Bemerkung zu der Berechnung der Aequator-Constanten, nebst Anwendung auf Comet I, 1866. Gylden.	The same.
	Annalen der Sternwarte in Leiden. Herausgegeben von Dr. Kaisir. Erster Band. Harlem, 1868.	Dr. Kaisir, Director of Observatory, Leiden.
	Ueber einen neuen Apparat zur absoluten Bestimmung von persönlichen Fehlern bei astronomischen Beobachtungen. Von F. Kaisir. Amsterdam, 1867.	The same.
	Verslag van den Staat der Sterrewacht te Leiden, en van de aldaar volbragte Werkzaamheden, in het Tidjvak van den ersten 1864–1868.	The same.
	Enige Opmerkingen omtrent de periodieke Fouten van Mikrometerschroeven naar Aanleiding van de jongste Ondersoekungen aan de Sterrewachte te Leiden. F. Kaisir. 1867.	The same.
	Rapport omtrent de tweede algemeene Bijeenkomst der Gemagtigden voor de Graadmeting in Europa, uitgehagt door F. Kaisir. 1867.	The same.
19	Proceedings of the American Academy of Arts and Sciences. Vol. VII, pp. 345–525.	The Secretary of the American Academy of Arts and Sciences, Boston.
	Mittheilungen aus Justus Perthes' geographischer Anstalt. No. XI, 1868.	Justus Perthes, Gotha.
	Proceedings of the Royal Geographical Society, London. Vol. XIII, No. 5.	C. Markham and R. Major, Secretaries.
	De Eischen der Medewerking aan te ontworpen Graadmeting in Midden-Europa. Kaisir en Stuart.	F. Kaisir and L. C. Stuart, Leiden.
	Nederlandsch meteorologisch Jaarboek voor 1867. 2 vols........	Buys Ballot, Director Netherland Meteorological Institute, Utrecht.
	Sur la marche annuelle du thermomètre et du baromètre en Neerlande et en divers lieux de l'Europe, 1849–'59. Buys Ballot.	The same.
	Zeitschrift für Meteorologie. III. Band, Nos. 21–24. IV. Band, Nos. 1 und 2.	Dr. C. Jelinek, Vienna.
	On the Temperature of the Sea at the Surface near the South Point of Africa. Cornelissen.	J. E. Cornelissen, Royal Dutch Navy.
	Meteorologiske Iagttagelser paa Christiania's Observatorium. 1867.	The Director of the Meteorological Observatory, Christiania.
	Norsk meteorologisk Aarbog. 1867..............................	The same.
	L'origine des étoiles filantes. Bruck..........................	R. Bruck, Major du Génie, Bruxelles.
	Traité élémentaire des fonctions elliptiques, par Dr. O. J. Brosch. 2 fasc.	Dr. O. J. Brosch, University of Christiania.
	Untersuchungen über die Beobachtungen von Bessel und Schlüter am Königsberger Heliometer zur Bestimmung der Parallaxe von 61 Cygni. Auwers,	Dr. A. Auwers, Berlin.
March 1	Beobachtungen an der kaiserlich-königlichen Central-Anstalt für Meteorologie. December, 1868,	Dr. C. Jelinek, Vienna.
	Telegraphische Witterungsberichte. Januar-Mai 1868	The same.
12	Bolletino meteorologico ed astronomico del reale osservatorio di Torino. Anno 1868.	Prof. A. Dorna, Director, Turin.
	Meteorological Papers compiled by Rear-Admiral Fitzroy. Nos. 10, 11, 12.	Mr. R. H. Scott, Director, Meteorological Office, London.
	Meteorological Papers published by the Board of Trade, 1862, (to No. 14).	The same.
	Meteorological Papers published by the Meteorological Office. 1863–'64.	The same.
	Barometer Manual. 1863....................................	The same.
	Coast Barometer Manual. 1863..............................	The same.
16	Mittheilungen aus Justus Perthes' geographischer Anstalt. 1866, No. XI. 1868, No. XII. Ergänzungsheft 19 und 25.	Justus Perthes, Gotha.
	Journal of the Scottish Meteorological Society. Nos. 1 to 21, except 5 and 6.	Alex. Buchan, Esq., F. R. S., Edinburgh.

Date.	Publications.	From whom received.
March 16	Denkschriften der kaiserlichen Akademie der Wissenschaften. Band XXVIII.	Prof. A. Schrötter, General Secretary, Vienna.
	Nova acta regiæ societatis scientiarum Upsaliensis. Serei tertiæ. Vol. VI, fasc. II. 1868.	Prof. A. J. Ångström, Secretary, Upsala.
	Meteorologische Beobachtungen angestellt auf der Leipziger Universitäts-Sternwarte im Jahre 1867.	Dr. C. Bruhns, Director, Leipzig.
	Résumé météorologique des années 1866 et 1867, pour Genève et le Grand St. Bernard. Plantamour.	Prof. E. Plantamour, Geneva.
	Ueber die Bahn des am 30. Januar 1868 beobachtenden und bei Pultusk im Königreiche Polen als Steinregen niedergefallen Meteors durch die Atmosphäre.	Prof. Dr. J. G. Galle, Breslau.
	Schweizerische meteorologische Beobachtungen. 1865, and Januar, Februar, 1868.	Prof. Dr. R. Wolf, Zurich, Switzerland.
17	Contributions to Terrestrial Magnetism. No. XI. Lieutenant-General E. Sabine.	Mr. R. H. Scott, Director of the Meteorological Office, London.
April 21	Beobachtungen an der kaiserlich-königlichen Central-Anstalt für Meteorologie. Jan., Feb. 1869.	Dr. Jelinek, Vienna.
	Telegraphische Witterungsberichte. February, 1869	The same.
23	Specimens of Curves furnished by the Self-recording Instruments at the Observatories established by the Meteorological Office.	Mr. R. H. Scott, Director, London.
27	Traité élémentaire des fonctions elliptiques. 2d part. Brosch	Dr. Brosch, Christiania, Norway.
	Oversigt over det kongelige-danske Videnskabernes. Nos. 1 and 2. 1868. Steenstrup.	J. Japetus Smith Steenstrup, Copenhagen.
	Schweizerische meteorologische Beobachtungen. März, April, Mai, 1868.	Dr. R. Wolf, Zurich.
	Journal of the Scottish Meteorological Society. January, 1869	A. Buchan, Esq., Secretary, Edinburgh.
	Proceedings of the Royal Geographical Society. Vol. XIII, No. 1	H. W. Bates, Secretary, London.
	Transactions of the Royal Society. Vol. 158, parts 1 and 2	Prof. W. H. Miller, Secretary, Cambridge.
	Proceedings of the Royal Society. Nos. 101 to 110	The same.
	List of Fellows, to November 30, 1869	The same.
	Mittheilungen aus Justus Perthes' geographischer Anstalt. 1869. Nos. I, II.	J. Perthes, Gotha.
	Vierunddreissigster Jahresbericht des Mannheimer Vereins für Naturkunde. 1868.	Dr. E. Weber, Vice-President of the Society of Natural Sciences, Mannheim.
	Abhandlungen der Akademie der Wissenschaften zu Berlin. 1867	E. E. Knemmer, Secretary, Berlin.
	Transits of Venus, 1874 and 1882. Airy.	G. B. Airy, Esq., F. R. S., Director Royal Observatory, Greenwich.
	Bulletin de la société de géographie. Février 1869	C. Maunoir, Secretary, Paris.
May 4	Intorno al magnetismo traversale alla direzione della corrente elettrico.	Prof. C. F. Zantedeschi, Padua.
	Incertezze della livellazione barometrica e geodetica	The same.
	Zeitschrift der österreichischen Gesellschaft für Meteorologie. No. 9. 1868.	Dr. C. Jelinek, Vienna.
7	Summary of Meteorological Observations at Brisbane, Queensland, Australia. January, 1869.	E. MacDonnell, Meteorological Observer, Brisbane, Queensland, Australia.
15	Weather Reports. July 1 to December 31, 1868	Meteorological Office, R. H. Scott, Director, London.
25	Tables to Facilitate the Reduction of Places of the Fixed Stars. Prepared for the American Ephemeris and Nautical Almanac.	Prof. J. H. C. Coffin, U. S. N., Superintendent Nautical Almanac.
June 1	Bulletino meteorologico dell Reale Osservatorio Collegio Carlo Alberto. Vol. IV, Nos. 1, 2, and 3.	Director Royal Observatory College Carlo Alberto, Moncalieri.
	Zeitschrift der österreichischen Gesellschaft für Meteorologie. 1868. No. 10.	Dr. C. Jelinek, Vienna.
	Beobachtungen an der kaiserlich-königlichen Central-Anstalt für Meteorologie. März 1869.	The same.
	Telegraphische Witterungsberichte	The same.
	Discorso del Comm. Cristoforo Negri, presidente della Societa Geographica Italiana.	Comm. Cristoforo Negri, Florence.
	Annual Address delivered before the Cincinnati Astronomical Society, June, 1845, by E. D. Mansfield, Esq.	Prof. C. Abbe, Director of the Cincinnati Observatory.
	Oration before the Cincinnati Astronomical Society, on laying the Corner-stone of the Observatory, by John Quincy Adams, November 10, 1843.	The same.
	Planet- och Komet-Observationer anställda År 1868 på Lund's Observatorium. Utgifna A. Möller.	Prof. Axel Möller, Lund, Sweden.
5	Bulletino meteorologico del Reale Osservatorio di Palermo. Vol. IV, Nos. 3 to 9.	G. Cacciatore, Director of the Observatory.
23	Proceedings of the Royal Geographical Society. Vol. XIV, No. 1	H. W. Bates, Esq., Editor.
	Beobachtungen des meteorologischen Observatoriums auf dem Hohenpeissenberg. Von 1851–'64. Lamont.	Dr. J. Lamont.
	Monatliche und jährliche Resultate zu der königlichen Sternwarte bei München von 1857 bis 1866.	The same.
	Proceedings of the Literary and Philosophical Society of Liverpool. 1865–'66. Nos. 19, 20, and 21.	J. C. Redish, Honorary Secretary, Liverpool.
	Mittheilungen aus Justus Perthes' geographischer Anstalt. 1869. No. III, und Ergänzungsheft No. 27.	Justus Perthes, Gotha, Germany.

Date.	Publications.	From whom received.
June 23	Sitzungsberichte der königlich-bayerischen Akademie der Wissenschaften zu München. 1867, Band II, Heft 3 und 4; 1868, Band I, Heft 1, 2, 3, 4; Band II, Heft 1, 2, 3, 4.	C. Wiedman, Secretary Royal Bavarian Academy of Sciences, Munich, Bavaria.
	Note sur les étoiles filantes du mois de Novembre 1868, par M. Ad. Quetelet.	M. Ad. Quetelet, Director of the Royal Observatory, Brussels.
	Annuaire de l'observatoire royal de Bruxelles, par M. Ad. Quetelet, directeur. 1869. 36me année.	The same.
	Sur la différence de longitude entre les observatoires de Leyde et Bruxelles. Quetelet.	The same.
	Observations des phénomènes périodiques pendant les années 1865 et 1866. A. Quetelet.	The same.
	Progrès des travaux statistiques, par M. Ad. Quetelet	The same.
	Physique sociale; ou, essai sur le développement des facultés de l'homme. A. Quetelet. Tome I.	The same.
	Bulletino meteorologico dell' osservatorio del Reale Collegio Carlo Alberto in Moncalieri.	The Director of the Observatory of the Royal College Carlo Alberto, near Turin, Italy.
24	Telegraphische Witterungsberichte der kaiserlich-königlichen Central-Anstalt für Meteorologie und Erdmagnetismus. April, 1868.	Dr. C. Jelinek, Director Central-Anstalt, Vienna.
	Beobachtungen an der kaiserlich-königlichen Central-Anstalt. April, 1869.	The same.
	Determination of Heights, chiefly in the interior of Continents, from Observations of Atmospheric Pressure, by A. Buchan, Esq., Secretary of the Scottish Meteorologieal Society.	A. Buchan, Esq., Secretary, Edinburgh.
July 6	Observaciones magnéticas y meteorologicas hechas por los alumos del colegio de Belen de la compania de Jesus en la Habana. 30 Noviembre 1867 a 30 Noviembre 1868. Habana, 1869.	The Director of the Magnetic and Meteorological Observatory, Havana.
24	Termografia-agghiacciamento. Memoria del Prof. A. B. Cav. Zantedeschi letta nella pontificia accademia Tiberina dal Pres. Annuale. Prof. Cav. A. Betocchi nella tornali del 18. Gennaro 1869.	Prof. Cav. Zantedeschi, Padua.
	Summary of Meteorological Observations at Brisbane, Queensland, Australia, during February and March, 1869.	E. MacDonnell, Observer, Queensland.
	Œuvres de La Grange, publiées sous les auspices de son excellence le ministre de l'instruction publique. Tomes 2m et 3me.	The Minister of Public Instruction, Paris.
	Monthly Meteorological Register at the Magnetic Observatory, Toronto, Canada. January to July, 1868.	G. T. Kingston, Director, Toronto.
	Monthly Absolute Values of the Magnetic Elements. 1865–1868	The same.
26	Curvas que representan la marcha de los instrumentos meteorometricos durante el mes de Dec. 1868; Jan., Feb., Mar. 1869.	The Director of the Observatory of the City Athenæum of Manila.
27	Schweizerische meteorologische Beobachtungen. June, July, and August, 1868.	Dr. R. Wolf, Zurich.
	Sitzungsberichte der kaiserlichen Akademie der Wissenschaften: Mathematisch-naturwissenschaftliche Classe. Band LVII, IV. Heft, 1. und 2. Abtheilung; Band LVII, V. Heft, 1. und 2. Abtheilung; Band LVIII, 1. Heft.	Prof. A. Schrötter, General Secretary, Vienna.
	Nederlandsch meteorologisch Jaarboek voor '68. (Part 1. Triplicate.)	Buys Ballot, Utrecht.
	Jahrbücher der kaiserlich-königlichen Central-Anstalt für Meteorologie. VI. Band. 1854.	Dr. Karl Hornstein, Director, Prague.
	Annales de l'observatoire impériale de Paris. Mémoires. Tome IX.	U.-J. Le Verrier, Director.
	Berichte der zur Beobachtung der totalen Sonnenfinsternisso des Jahres 1868 nach Aden unternommenen österreichischen Expedition. I. Bericht. IV, V.	A. Schrötter, General Secretary, Imperial Academy, Vienna.
	Annalen der kaiserlich-königlichen Sternwarte in Wien. Fünfzehnter Band. 1865.	Dr. Karl von Littrow, Vienna.
	Beiträge zu Littrow's Kalender, 1869. Sternschuppen und Kometen.	The same.
	Beitrag zur Climatologie von Aden. Weiss	The same.
	Beiträge zur Kenntniss der Sternschuppen. Weiss	The same.
	Bestimmung der Meridiandifferenz Leipzig–Doblitz für die von Herrn General-Lieutenant J. J. Bayer vorgeschlagene mitteleuropäische Gradmessung. C. A. von Littrow. Wien, 1868.	The same.
	Magnetische und Meteorologische Beobachtungen. Kaiserlich-königliche Sternwarte zu Prag. 1868. Hornstein und Nurmann.	Dr. Karl Hornstein, Director, Prague.
31	Mittheilungen aus Justus Perthes' geographischer Anstalt 1869. Nos. IV, V. Ergänzungsheft No. 26.	Justus Perthes, Gotha.
	Atlas météorologique de l'observatoire impériale. 1867	U.-J. Le Verrier, Directeur de l'Observatoire.
	Atlas des mouvemens généraux de l'atmosphère. 1865	The same.
August 5	Notes and Queries. July 24, 1869	Science and Art Department of South Kensington Museum, London.
	Ueber eine bisher unbenutzte Quelle magnetischer Declinations-Beobachtungen. C. Doppler.	C. Doppler, Vienna.
10	Bulletino meteorologico del Reale Collegio Carlo Alberto in Moncalieri. Vol. IV, No. 5.	The Director of the Observatory of the Royal College Carlo Alberto, Moncalieri.
	Tafeln der Pomona mit Berücksichtigung der Störungen durch Jupiter, Saturn, und Mars. Lesser.	The Secretary of the German Astronomical Association, Leipsic.
	Vierteljahrsschrift der astronomischen Gesellschaft. IV. Jahrgang, 2. Heft.	The same.

Date.	Publications.	From whom received.
August 10	Le stelle cadenti dei periodi di Agosto e Novembre 1866, di Agosto 1867, di Novembre 1867.	Director of the Observatory of the Royal College Carlo Alberto, Moncalieri.
	Bulletino meteorologico Reale Collegio Carlo Alberto. Vol. I, II.	The same.
	Report to the Board of Visitors of the Royal Observatory, Greenwich. Read at the annual visitation, June 5, 1869.	G. B. Airy, Esq., Astronomer-Royal, Greenwich.
	Beobachtungen an der kaiserlich-königlichen Central-Anstalt für Meteorologie und Erdmagnetismus. June, 1869,	Dr. C. H. Jelinek, Vienna.
25	Charts showing the Surface-Temperature of the South Atlantic Ocean for each month of the year.	R. H. Scott, Director of the Meteorological Office, London.
	Weather Reports to June 30, 1869	The same.
	Tidal Charts of the Atlantic Ocean	Capt. G. H. Richards, Hydrographic Office, London.
Sept. 1	Photographs of the Eclipse of the Sun of August 7, 1869, taken by the Academy of Natural Sciences at Davenport, Iowa.	W. H. Pratt, Secretary of the Academy of Natural Sciences, Davenport.
	Report of Observations of the Eclipse by Prof. D. S. Shelden	The same.
Oct. 10	Forsok till Bestämnig af Precessionskonstanten medelst Ljussvaga Stjernon. M. Nyren.	M. Nyren, Upsala, Sweden.
	General Meteorological Register, for the year 1868, of the Magnetical Observatory, Toronto, Ontario.	Mr. T. G. Kingston, Director of the Magnetical Observatory.
	Monthly Meteorological Register at the Magnetical Observatory, Toronto, Ontario. September, October, November, December, 1868.	The same.
	Telegraphische Witterungsberichte der kaiserlich-königlichen Central-Anstalt für Meteorologie und Erdmagnetismus. July and August, 1868.	Dr. C. H. Jelinek, Director of the Central Meteorological Institute, Vienna.
	Zeitschrift der österreichischen Gesellschaft für Meteorologie. IV. Band, 16 Nos.	The same.
	American Ephemeris and Nautical Almanac. 1871	Prof. J. H. C. Coffin, Superintendent.
16	Bulletin de l'observatoire météorologique de Montsouris. Première partie, texte explicatif 1869; deuxième partie. July to August 13, 1869.	M. Chas. St. Clair Deville, Director of Observatory, Montsouris.
	Annotasioni alla topografia atmosferica della statistica Italiana teorica e pratica del Cav. Avv. Luigi Guala. Zantedeschi. Padova, 1869.	Prof. F. Zantedeschi, Padua.
	Report of the Meteorological Reporter to the Government of Bengal for 1867 and 1868.	H. J. Blanford, Esq., Meteorological Reporter, Calcutta.
25	Bulletin de la société de géographie. Août 1869.	C. Maunoir, Secretary, Paris.
26	Report of the Meteorological Committee of the Royal Society. December 31, 1868.	R. H. Scott, 116 Victoria street, London.
	Schriften der naturforschenden Gesellschaft zu Danzig. Neue Folge, zweiter Band, zweites Heft.	Prof. A. Menge, Secretary of the Society of Natural Sciences, Dantzic, Prussia.
	Meteorologiska Iakttagelser i Sverige, utgifina af koniglick-svenska Vetemskape Akademien. Sjette Bandet. 1864–'65–'66.	Dr. Ehrindhagen, Secretary Swedish Academy of Sciences.
	Normale fünftägige Wärmemittel für 88 Stationen, bezogen auf den 20-jährigen. Zeitraum 1848–'67.	Dr. Carl Jelinek, Vienna.
	Anleitung zur Anstellung meteorologischer Beobachtungen und Sammlung von Hülfstafeln. Jelinek.	The same.

REPORT

OF

REAR-ADMIRAL B. F. SANDS, U. S. N.

REPORT OF REAR-ADMIRAL B. F. SANDS, U. S. N

UNITED STATES NAVAL OBSERVATORY,
Washington, July 15, 1871.

SIR: The officers of the Observatory, detailed by the Navy Department for observations of the late eclipse of the sun of the 22d December, 1870, having returned from that duty, I have the honor to forward herewith their reports.

After the successful results of the observations of the eclipse of August 7, 1869, by the officers of this Observatory, it was desirable that their experience should be taken advantage of for the further elucidation of the subjects involved in such phenomena; and the eclipse to occur in Europe on the 22d December, 1870, was discussed with a view to their taking part in the observations on that occasion, as one of the legitimate and appropriate duties of the Naval Observatory.

The Navy Department was addressed by me upon the subject, which resulted in the detail for that duty of Professors Simon Newcomb, Asaph Hall, William Harkness, and J. R. Eastman, of the United States Navy, attached to this Observatory, all of whom had contributed largely to science by their reports of the August eclipse.

It was, at first, intended to have the parties accompanied by a skilled photographer and other observers not attached to the Observatory; but having no special appropriation for the purpose, and our contingent fund being too limited to meet the expense that would be incurred, we had to restrict ourselves to the officers of this institution already experienced in such observations.

The last three of the officers mentioned above were directed to proceed to Sicily, to occupy some convenient points near Syracuse, each in his distinct and separate duties, with independent instructions for each—Professor Hall for observations upon the corona, Professor Harkness for spectral analysis, and Professor Eastman with polarizing apparatus and meteorological instruments; with directions to avail themselves of any assistance they might be able to obtain in the localities selected.

Professor Newcomb, having been previously detailed for other special duties in Europe, was instructed also to occupy some point near Gibraltar for general observation of the eclipse and physical constitution of the corona, and other observations to determine the path of the center of the shadow over the earth, with the object of obtaining data for the correction of the lunar tables, by comparing these results with those previously calculated from them.

While in England, *en route* for his station, Professor Newcomb, through the courtesy of the Astronomer Royal, Mr. Airy, and of Sir James Anderson, the president of the Anglo-Mediterranean Telegraph Company, made very elaborate arrangements to correct the stations of our observers by cable for difference of time with the Greenwich Observatory. This was accomplished between Sicily and Malta and Gibraltar, and failed with Greenwich only in consequence of a break in the cable between that place and Lisbon, which could not be repaired during Professor Newcomb's sojourn at Gibraltar.

By special invitation, Professor Newcomb accompanied the English party to Gibraltar on board H. B. M. Steamer Urgent, arriving in time to make the necessary preparations for telegraphic difference of time with Greenwich, Gibraltar, and Malta.

Professors Hall, Harkness, and Eastman arrived at Syracuse with their instruments in ample time to make every preparation, and selected their several positions near that city. Mr. Hall and Mr. Harkness, in the mean time, at Malta and Syracuse respectively, in connection with Mr. Newcomb at Gibraltar, determined by telegraphic cable the difference of time between those places. Cloudy weather with high winds made the Sicily observations less successful than we had hoped, but they tend to corroborate those of our parties in America on the 7th August, 1869, and form interesting addenda to those of that year on this continent.

In accordance with the course I had adopted in the administration of the duties of Superintendent, to give to each of the officers the full credit of his work, and that they may share the responsibility attendant upon their observations, I have the pleasure to forward to the Department their very interesting reports

entire, and over their several signatures. Constituting as they do very valuable contributions to the science of astronomy, evincing great ability and personal interest in the subject, most creditable to the observers and highly honorable to the institution of which they are prominent members, it would be unjust to the officers, and detract from the merits of the reports, to abridge or condense them.

The letter of Captain Tupman, R. M. A., who volunteered to assist Professor Harkness, containing his notes and other remarks, is also given entire at the end of Professor Harkness's report. The reports have been delayed to this date by the severe illness of Mr. Harkness in Europe, and the detention of Mr. Newcomb by other duties on which he was engaged, and which were protracted by the war in Europe.

It is most gratifying to record here the very great courtesy and kindness extended to our officers by the savants of Great Britain and the continent—setting aside national jealousies and forming one great brotherhood of science. To each of those learned and distinguished gentlemen I have had the pleasure to address a letter expressing my appreciation of the attentions thus shown. They are mentioned by name in the several reports of our officers.

Through the courtesy of the Secretary of State, Hon. Hamilton Fish, we secured the ready acquiescence of the foreign legations of England and Italy for the passage of the instruments used through the several custom-houses.

I have the honor to be, very respectfully, your obedient servant,

B. F. SANDS,
Rear-Admiral, Superintendent.

Hon. G. M. Robeson,
Secretary of the Navy, Washington City.

REPORT

OF

PROFESSOR SIMON NEWCOMB, U. S. N.

REPORT OF PROFESSOR NEWCOMB, U. S. N.

BERLIN, *March* 21, 1871.

COMMODORE: I have the honor to present the following report of my observations of the total solar eclipse of December 22, last, made in compliance with the orders of the Honorable Secretary of the Navy. As my proceedings were necessarily determined by the character of the observations to be made, I ask leave to begin by calling to your mind the plan of work marked out for me.

The great number of spectroscopic parties, who were expected to take part in the observations, made it desirable to choose some less occupied, though, it might be, less brilliant field. It was therefore determined that I should simply scrutinize the physical constitution of the corona, as it appeared through the telescope employed in the observations of partial phase. The question kept more particularly in mind was one respecting which the testimony of previous observers is very discordant, namely, whether there is any appearance of structure in the formation of the corona, or whether its different parts seem to run into each other by insensible gradations; in other words, whether the corona is composed of bright points, filaments, and rays, or whether its light is soft and milky. In the former case, it would be proved that the corona could not result solely from an elastic atmosphere surrounding the sun, while in the latter this question might still be an open one.

Another object was to determine, with as much accuracy as possible, the path of the center of the shadow over the surface of the earth, and the time of its passing a given point, in order to compare these results with those previously calculated from the lunar tables, and thus obtain data for the correction of the latter. The relative positions of the sun and moon can indeed be determined by observations of an eclipse at points far removed from the central line. But the observations for this purpose, as usually made, are subject to various unavoidable sources of error, which it is not necessary to enumerate. On the other hand, when the observer is on or near the line of central eclipse, observations for this purpose can be made with great precision, and my arrangements were planned with the view of putting in practice a very accurate method of observation, which, if not new, has fallen into almost complete desuetude. This method is founded on the geometrical theorem that the line joining the cusps of the partially eclipsed sun is at right angles to the line joining the centers of the sun and moon, so that the angle of position of the latter line can be immediately inferred from that of the former. The advantages of the method arise from the great extent to which the errors of the ordinary class of observations may thus be diminished. During the last century, observations of solar eclipses have been generally confined to determinations of the times of contact of the limb of the moon with that of the sun or with spots on its surface. The latter furnish no data for fixing the position of the moon, because the positions of the spots are never accurately known. The former generally consist of observations of external contact, or moments of the beginning and end of the eclipse. But if we consider the question with mathematical accuracy, we must admit that an actual external contact of the limb of the moon with that of the sun cannot be observed, because the former cannot be seen until it has impinged on the latter to an appreciable extent. If the magnitude of this extent were constant, it could be easily determined and allowed for. But, unfortunately, it is a very variable and uncertain element, depending on the observer, the telescope, and the nature of the moon's surface, smooth or rough, at the point of contact. Observations of last contact are indeed less in error from this cause than those of first contact, but they still exhibit very large discrepancies.

Observations of internal contact in annular and total eclipses are free from the source of error here considered. But they are still subject to the uncertainties arising from the inequalities of the moon's surface; and when made, as is usually the case, at points near the line of central eclipse, they afford no data whatever for determining the error of the moon's latitude, or the path of the line along the earth's surface. To be useful for this purpose, observations of contact must be made at points near the limits of annular or total phase. We have occasional observations so made at public or private observatories, which chanced to lie in the proper position relatively to the moon's shadow; but I know of only two total eclipses in which systematic arrangements were made to determine by observation the path of the moon's shadow along the sur-

face of the earth. These were the eclipses of 1715, in which the moon's shadow passed over England, and that of 1869, in which it passed over the United States. The method adopted in the latter was substantially identical with that employed by Halley in the former, and consisted in securing observations of the simple duration of total phase by intelligent inhabitants at various points near the limits of totality. Though this method is the best yet used, it is not always satisfactory or practicable. The limits of the shadow are themselves rendered uncertain by the irregularities of the moon's surface, besides which we require an accurate knowledge of the positions of all the observers before the observations can be utilized. Of course the observations can be made only in those rare cases when the shadow passes over a well-populated country. But knowing from observation the angle of position of the line joining the center of the sun and moon at any moment, we can thence infer the direction of the center of the shadow at that moment. By making a number of determinations of this angle, as seen from any point in or near the shadow while the latter is passing, the path of its center can thence be inferred with great accuracy. It is true that the error of any isolated measure arising from inequalities of the moon's surface will be of the same magnitude with that of an observed contact. But all the measures being made on different parts of the moon's contour, as the solar crescent seems to move around the moon, the errors arising from irregularity of contour will be almost entirely eliminated from the mean result. My trial of this method convinces me that the observations of the sharp cusps can be made with even greater precision than I had anticipated.

The direct determination of the line joining the cusps is, however, scarcely practicable, owing to the breadth of the solar disk, which prevents the observer from setting a wire simultaneously on the two cusps, unless the telescope be moved by clockwork and a low power be used. We have therefore to substitute differences of right ascension of the cusps, which may be obtained by observing transits of the two cusps over the wires of an equatorially mounted telescope. This was the mode of observation actually adopted, the telescope employed being the comet-seeker of the Observatory. The instrumental arrangements will be more fully described in connection with my observations, which I shall preface with an account of the preliminary operations made to secure the success of the proposed plan.

I sailed from New York, in compliance with my orders, and reached London on November 1st. My instructions left me at liberty to select that point along the line of totality the longitude of which could best be determined by the electric telegraph, an accurate longitude being required before my observations could be used. Immediately on my arrival in London I therefore sought an interview with the Astronomer Royal, to confer with him respecting the choice of a station, and to request his co-operation in the work of determining the longitude of such station as might be selected. It was soon found that Gibraltar was in this respect the most favorable point along the path of totality, as it was in direct telegraphic communication with England through the Falmouth, Gibraltar and Malta cable. The Astronomer Royal entered into my plans in the most obliging manner, agreeing to send time-signals from the Royal Observatory to my station whenever the two points could be put in telegraphic communication, and using his influence to secure such communication. To attain this end, he introduced and recommended me to the engineer-in-chief of the government telegraphs, R. S. Culley, Esq. Mr. Culley most cordially tendered us the use of any of the telegraph lines that might be under his control. It only remained to ask for the use of the cable, and this I did in conjunction with Mr. G. W. Dean of the Coast Survey, who had been instructed by Professor Peirce to co-operate with our parties whenever the interests of science could be so advanced, and whose experience in telegraphing longitude-signals through the ocean-cables made his counsel of great value. We arranged for an interview with Sir James Anderson, managing director of the cable, on the following Monday. At this interview, the distinguished director expressed the great pleasure it would give him to do everything in his power to insure the success of our observations, and offered to place the cable at our disposal at such times as we might require it for the transmission of signals. As the cable was least loaded with business on Sunday afternoons and Monday mornings, it was agreed to select these times for transmission if weather permitted of our correcting our chronometers by astronomical observations.

It only remained to frame a plan of operations for the transmission of signals, which I did, after consultation with the Astronomer Royal and Mr. Dean. The unfortunate failure of the scheme through a cause beyond human foresight and control deprives both my plan and my further proceedings under it of nearly all their interest. However, I inclose a copy of the plan as evidence of the care with which the operations were arranged. To guard as far as possible against all possibility of failure, Sir James Anderson advised me to visit the telegraph office at Porthcurno, the terminus of the cable, and assure myself that all the arrangements for transmitting signals were properly made and understood by the operators. I started on this journey

December 2d, and on the very same day I was advised that a fault had occurred in the cable between Lisbon and Gibraltar. As it was expected that the fault would be speedily found and repaired, I made no change in my plan of operations, and completed the proposed journey. The hope in question was, however, not realized, so that no time-signals could be transmitted at all. The failure of the cable at this moment was most unfortunate for us, because, had I not fully expected to obtain a telegraphic longitude, I should have tried to organize a chronometric expedition for the same purpose, and, I believe, would have succeeded. But it was now too late to do so; indeed, I did not return to London at all after my visit to Penzance.

During my stay in London a joint committee of the Royal and Royal Astronomical Societies was engaged in organizing an expedition for the observation of the eclipse. Having secured from their government the grant of a ship, they invited me to accompany them to Gibraltar. I accepted this flattering invitation, and therefore proceeded from Porthcurno direct to Portsmouth, the port of departure. We sailed on Tuesday, December 6th, in H. B. M. Ship Urgent, on which I was, during a week, the guest of the English expedition. We reached Gibraltar, after a rough passage, on the morning of December 14th.

I first called on the American consul, H. J. Sprague, Esq., and made known to him the object of my visit. He informed me that my instruments, which had been forwarded by the consul at Liverpool, had arrived in safety. I then called on Mr. De Sauty, superintendent of the Gibraltar office of the telegraph company, and learned that Professor Hall was awaiting me at Malta in order to exchange time-signals. I arranged for the exchange on the two following days.

The business next in order was to make the object of my visit known to the authorities. Accordingly, on Friday, Mr. Sprague presented me to His Excellency Sir W. F. Williams, of Kars, the governor of the fortress, who most obligingly tendered me every facility in his power for making my observations from any station I might select within his jurisdiction. The selection of a station was, however, no easy matter. None of the authorities I consulted advised a point within the town, for the reason that during an east wind the latter is always covered with fog, though the sky may be clear both to the north and the south. A station far enough north to avoid this evil would be on Spanish soil and would be subject to several inconveniences, one of which would be the impossibility of any communication with the telegraph office or the town at night. A station to the south was objectionable because farther removed from the line of central eclipse, which passed some twenty miles north of Gibraltar. As this seemed to be the least of the evils, I selected a point known as Buena Vista, about half-way between the town and Europa Point. Its position relatively to some other points in the fortress was as follows, the distances being given in round hundreds of feet, as measured on a large map:*

8,800 feet south and 1,400 feet east of telegraph office.
6,900 feet south and 800 feet east of American consul's house, Edward's Road.
5,600 feet south and 1,100 feet west of Signal Tower.
2,700 feet south and 2,000 feet east of base of new mole.

According to the Admiralty Chart of 1864, the position of the flag-staff near the latter point is latitude $36° 7' 10''$; longitude $0^h 21^m 25^s.1$ W.† This would make the position of my station

Latitude, $36° 6' 43''$ N.
Longitude, $0^h 21^m 23^s.4$ W.

The latitude derived from my sextant observations is

$$36° 6' 51'',$$

with a probable error of four or five seconds. The difference of eight seconds is quite unimportant in the case of the eclipse observations.

Having signified my choice of a station to the governor, his excellency immediately directed that I should be supplied with anything in the shape of military stores I might require. I thus received everything necessary for the protection of my instruments, including tents and a guard.

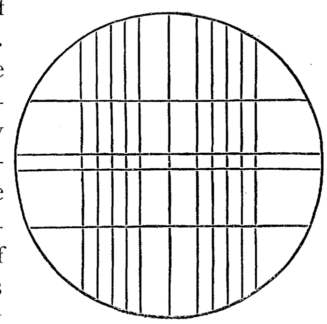
The instruments were conveyed to the station on Saturday, and the work of getting them into position was commenced on Monday. They consisted of the observatory comet-seeker, which was fitted up for the observation of the eclipse itself; a small portable transit, by Würdemann, of about two inches aperture,

*There is probably an error of about 5° in azimuth in these measures, the direction of the supposed meridian being really N. 5° W. and S. 5° E.

†The chart of July 27, 1869, gives a longitude 2^s less.

made for the Northwestern boundary survey, and loaned to the expedition by the Chief of Engineers of the Army. For the determination of latitude and time I had also a Gambey sextant with artificial horizon.

The comet-seeker is an equatorially mounted telescope, of thirty-two inches focus and four inches aperture. When turned on the sun the aperture has to be reduced to two inches or less, owing to the intensity of the heat concentrated at the eye-end when the full aperture is used. Its small size is partly compensated for by its fine definition. A power of forty was selected for the observation of the eclipse. The eye-piece was furnished with a diaphragm of eleven vertical and four horizontal wires, arranged as in the accompanying diagram, by Mr. Gardner, instrument-maker at the United States Naval Observatory. The intervals between the closer vertical wires are approximately each $2\frac{1}{2}'$ of arc, or 10^s of time, while the wider intervals on each side of the center wire are $5'$ of arc. The extreme distance between the outside wires is therefore $30'$, or a little less than the Sun's diameter. The eye-piece could be turned into any required position, so that the term vertical, as applied to the eleven wires, is only a relative one. A notch was cut into the eye-piece to indicate a fixed position of the latter in which the central wire coincided accurately with the meridian of the instrument. There was no other means of fixing or determining the angle of position of the wires. The direction of the polar axis of the instrument admitted of no adjustmenr for latitude; but Gibraltar being less than three degrees south of Washington, it was easy to elevate one side of the base of the instrument enough to secure the adjustment in question. Both axes of the instrument have divided circles, and each circle is read by two opposite verniers, which give single minutes in declination and spaces of four time-seconds in R. A.



The transit-instrument was mounted on a cast-iron stand. For the adjustment of level and azimuth one Y was movable horizontally and the other vertically. Both movements were effected by micrometer-screws with divided heads, a feature very convenient for the determination of the instrumental constants. The reticule consisted of seven vertical and two horizontal wires. The instrument was supplied with two spirit-levels for leveling the axis.

As it was not easy to get solid stone piers for the instrument, I adopted the plan of using the outside packing-cases, well packed with sand, for the supports. For the transit the box was packed slightly more than full, so that when the top was nailed down its upper surface was rendered slightly convex by the pressure of the sand below. The stability of the instrument, though ample to determine the local time for observation of the eclipse, would not have sufficed for any accurate astronomical determination.*

The comet-seeker was mounted under a tent in such a way that by slightly changing the position of the latter through its supporting cords the instrument could be either entirely covered in, or could be left far enough out to command the southern half of the heavens. On the day preceding the eclipse I got it adjusted to the diurnal motion of the earth as nearly as seemed practicable with the rough means at my disposal. The reticule was adjusted on a distant object, so that the middle right ascension wire was as nearly as possible in the plane of motion of the instrument in declination; after the adjustment was made, however, the top of the wire seemed to incline to the east by the smallest appreciable amount. In the day and evening observations were made to determine such of the instrumental errors as it was necessary to know. During this entire day the sky was cloudless, and everything gave promise of a fine day for the eclipse.

The morning of the 22d dawned with equal promise. At 8 o'clock only a few light and fleecy clouds were to be seen in the sky. A little before nine I observed the transit of β Ursæ Minoris with the transit-instrument. But before I could get another observation clouds began to cover the sky, and an hour before the time of commencement of the eclipse the southern heavens were covered with clouds, mist, and fog, which came in from the Atlantic. There was still much blue sky to be seen in the north, so that I thought I should have done better to observe from the town. In another half hour this had also disappeared, the instruments had to be covered to protect them from the rain, and the prospect seemed hopeless. But a short time before the commencement, fugitive glimpses of the sun began to be obtained through the clouds. I took my seat at the telescope and got a very good view of first contact at $22^h\ 52^m\ 35^s$, chronometer time.

* To each error of one second in the determination of time would correspond an error of $0''.4$ in the longitude of the moon deduced from the observation. The instrument was steady enough to give the local time certainly within a fourth of a second, so that the deduced longitude of the moon could not be $0''.1$ in error from this cause.

This was the moment at which I began to see the limb of the sun indented by the rough edge of the moon. The actual first contact must have occurred an appreciable time, probably two or three seconds, sooner. I then turned the eye-piece so that the R. A. wires of the eye-piece were at right angles to the chord of the eclipsed portion of the sun, and noted the moments at which the length of the chord was measured by certain wire intervals. These observations were rendered difficult and uncertain by the flying clouds, which would at one moment shut the sun off entirely and at another suddenly let him shine with full brilliancy. However, I give the observations *in extenso* in the accompanying papers.

Again the sun was completely hidden, and again the instruments had to be covered from the drizzling rain. Half an hour before the total phase, when I wanted to measure the cusps, the clouds again partially cleared away, so that I was able to obtain several sets of transits of the cusps over the R. A. wires of the comet-seeker between and through the rapidly driving clouds. For this purpose, the eye-piece was restored to its vertical position by the notch made for that purpose.

During the five minutes preceding the total phase the prospect of seeing the latter looked as dark as ever. Once more, however, the clouds broke up at the critical moment. A minute or two before the disappearance of sunlight, what little was left of the sun appeared through the clouds, and I again turned the eye-piece so as to measure with the R. A. wires the length of the vanishing crescent, having first removed the cap from the telescope so as to see with the full aperture of four inches. But in the hurry and confusion of the moment I did not get a measure. I noticed, however, that when the crescent was reduced to about 90°, the ends began to break off and disappear. This process went on with increasing rapidity until $0^h\ 18^m\ 35^s$ chronometer, when all that remained of the crescent was broken up throughout its entire length. The fragments thus formed disappeared one by one, and the last one vanished at $0^h\ 18^m\ 37^s$. I judge that the true time of second contact should be considered about the mean of these two moments, or $0^h\ 18^m\ 36^s$.

As soon as I had recorded the time of disappearance I put my eye again to the telescope. Instead of the gorgeous spectacle I witnessed in 1869, I saw only the most insignificant corona, although the full aperture of the telescope was used. Supposing that this was of course due to the clouds, I kept my eye at the telescope in hopes of their disappearance, still, however, scrutinizing the phenomena most carefully. I could not see the slightest trace of bright or dark points, rays, or filaments, the light everywhere seeming as soft and diffused as the zodiacal light. There were, indeed, as in former eclipses, great differences between the extent and brilliancy of the corona at different points, but all the parts seemed to shade into each other by insensible gradations. The protuberances on the eastern limb of the sun were numerous and brilliant, presenting the many fantastic forms which photography has rendered so familiar. But they presented no appearance of structure, as did the great protuberance in the eclipse of 1869. The light and color of all were sensibly uniform throughout their entire extent, and their outline was sharply defined. So far as I saw they were all of the red color so frequently described, a much brighter red than I saw at Des Moines. I cannot speak for minute differences of color or brilliancy, because I had not intended to make the protuberances a special object of scrutiny.

I waited in vain through the few moments of total eclipse for the corona to be seen more distinctly, and observed the reappearance of sunlight under the impression that the clouds had prevented me from seeing more than a very little of the corona. But, after finishing my observations, Mr. Sprague and Mrs. Newcomb, both of whom were outside of my tent, agreed in testifying that the sky in the direction of the sun seemed quite free from clouds during the entire total phase, and that two stars were distinctly visible in the neighborhood of the sun. It is a little singular that while the two parties agree in describing the positions of the stars, their descriptions are not reconcilable with the positions of Venus or Saturn, the only bright planets in the neighborhood of the sun. I bring this forward as tending to excite suspicion that the corona is subject to very great changes of brilliancy, a suspicion, however, which can be removed or confirmed only by the observations of others. My own testimony is simply this: the corona of 1869, through a haze which rendered all but the brightest stars invisible to the naked eye, seemed to me many times more brilliant than that of 1870, seen through an atmosphere which permitted at least the brighter planets to be seen.

The first ray of returning sunlight appeared at $0^h\ 20^m\ 27^s$, chronometer. It appeared at several points of the moon's limb in such rapid succession that I could not designate an exact moment in which the crescent seemed broken up as it did 2^s before the disappearance of sunlight. During the succeeding minute I succeeded in getting three measures of the length of the crescent, but they were by no means satisfactory.

I then set the eye-piece into position for observing transits, and during the half hour following observed nine sets of transits very satisfactorily indeed. Clouds as thick as ever then intervened, but cleared away

again in time to allow of a very satisfactory set of measures of chord during the few minutes preceding the last contact, and of the observation of last contact.

The failure of the longitude determination prevents me from giving a definitive reduction of my observations. I have no knowledge of the manner in which the Admiralty longitude already quoted was determined, or whether it is sufficiently accurate for astronomical purposes. Assuming, however, that this longitude is correct, the computed and observed times of the phases, and the resulting errors of the difference of tabular longitudes of the sun and moon, will be as follows:

Phase.	Greenwich times.			Local times.			Obs. times.	Δt	$\Delta \lambda$
	h.	m.	s.	h.	m.	s.	s.	s.	$''$
First contact . .	22	51	38.6	22	30	15.2	13.4	− 1.8	+ 0.7
Second contact .	0	17	40.8	23	56	17.4	14.4	− 3.0	+ 1.1
Third contact . .	0	19	29.8	23	58	6.4	5.4	− 1.0	+ 0.4
Fourth contact .	1	46	47.6	1	25	24.2	18.4	− 5.8	+ 2.2

This result would indicate a correction of $+1''.1$ to the longitude of the moon derived from Peirce's tables, supposing Hansen's tables of the sun to be correct. Comparing Hansen's lunar with Le Verrier's solar tables, the relative correction will be $-6''.4$, an amount which I can scarcely believe the error of Hansen's tables have reached.

In the accompanying papers I present the observations *in extenso*, with such preliminary reductions as I have been able to make. They are as follows:

A. The observed times of contact and the measures of chords near these times, which may serve to correct the latter.

B. The observed transits of the cusps over the wires of the comet-seeker, made to determine the difference of their right ascensions. To reduce these observations completely it is necessary to know the angle which the line of motion of the instrument at any point makes with the meridian. This requires a knowledge of four constants, the errors of collimation of the two axes of the instrument, and the hour angle and polar distance of the point in the heavens toward which the polar axis of the instrument is directed. The observations for this purpose are given in C.

D. The sextant observations for latitude of station, with a summary of the resulting values of the latitude. The error of eccentricity of the sextant being uncertain, a much greater weight has been given to the results of those dates when a north and south object were both observed.

E. Sextant observations for correction of chronometer, made before the mounting of the transit, completely reduced. The result of December 16th is discordant to a degree I cannot account for; it is difficult to suppose such a change to have actually taken place in the error of the chronometer.

F. Observations for index correction of sextant.

G. Transits observed with the transit-instrument, completely reduced.

H. The observations for determining the constants pertaining to the transit-instrument.

I. Exchange of signals with Professor Hall at Malta, through the Falmouth, Gibraltar and Malta cable.

A determination of the inclination of the separate wires of the comet-seeker is still wanting for the complete reduction of the transits of cusps, and the definitive determination of the path of the center of the shadow. This cannot be done till my return, when I hope to present you with the definitive results of my observations.

It has been my agreeable duty, both in this and in my preceding reports, to inform you of the numerous facilities and courtesies extended to me by the authorities of Great Britain. I have only to add, in general terms, that nothing could exceed the cordial and friendly spirit with which the objects of our expedition were everywhere received and promoted by all the authorities and people of that country with whom it was my good fortune to come into contact. It is also just that I should acknowledge the indebtedness of the expedition to Mr. Horatio J. Sprague, United States consul at Gibraltar, for his many exertions to secure its success.

Very respectfully, your obedient servant,

SIMON NEWCOMB,
Professor of Mathematics, U. S. N.

Commodore B. F. Sands, U. S. N.,
Superintendent U. S. Naval Observatory, Washington.

A.

Observed chronometer times of contact, and distances of cusps near the times of contact.

Chronometer times.			
h.	m.	s.	
22	52	35	First contact.
22	53	55.0	Chord reaches from wires IV½ to VI.

1	47	6½	" " " " III½ to V.
1	47	27	" " " " IV to V.
1	47	40	Last contact.

NOTE.—The measures of chord following first contact were rendered difficult and uncertain by the continual passage of flying clouds.

B.

Transits of the sun's cusps over the R. A. wires of the comet-seeker to determine the difference of their right ascension, and thence their angle of position and the angle of position of the line joining the centers of the sun and moon.

(Telescope east of axis.)

Cusp.	I.			II.	III.	IV.	V.	VI.	VII.	VIII.	IX.	X.	XI.

The eye-piece, with the diaphragm, was now turned back 90°, to observe the length of the small remaining crescent of the sun during the minute preceding the total phase.

After the total phase, it was returned (as was supposed) accurately to its original position, and the transits of the cusps were again observed, as follows:

At

$$0^{h}\ 23^{m}\ 11^{s}$$

the line joining the cusps was parallel to the R. A. wires.

It was now found that after the total phase the eye-piece was not returned accurately to its original position. While, before the total phase, the middle R. A. wire was very nearly parallel to the line of motion of the telescope in N. P. D., it was now found, by observation on a distant terrestrial mark, that the top of the middle wire deviated to the east by an amount which throughout the breadth of the field (about 1°) amounted to $\frac{1}{9}$ the distance of the closer wires, or about 17″, making the change of inclination about 0° 16′. The probable error of this estimate is about ⅙ its amount.

C.

Readings of circles when telescope is pointed on terrestrial marks in reversed positions of the instrument, made to determine the collimation errors of the telescope and the declination axis, and the index error of the declination-circle.

Mark.	Readings of declination—Verniers.		Readings of R. A.—Verniers.		Mean Vernier.	
	I.	II.	I.	II.	Dec.	R. A.
	° ′	° ′	h. m. s.	h. m. s.	° ′	h. m. s.
First mark	314 58	135 47	9 47 22	21 48 12	315 22	9 47 47
Tel. reversed . . .	224 30	45 24	21 47 44	9 47 24	224 57	21 47 34
Second mark . . .	308 0	128 56	10 17 2	22 18 0	308 28	10 17 31
Tel. reversed . . .	231 18	52 16	22 17 46	10 18 18	231 47	22 18 2
Third mark	8 22	189 15	18 25 18	6 25 42	8 48	18 25 30
Tel. reversed . . .	171 0	351 52	6 26 26	18 27 22	171 26	6 26 54

These readings give, for the index error e of the declination-circle,

First mark, $2e = -19'$
Second mark, $2e = -15'$
Third mark, $2e = -14'$
Mean, $e = -8'$

The following readings of the declination-circle, when the telescope was pointed on the center of the sun, were made to determine the error in the direction of the polar axis of the instrument:

Date.	Chronometer times.	Sun's hour-angle.	Readings of Verniers.		Telescope.	Resulting distance of pole of instrument from sun.	Pole of instrument beyond pole of the earth.
			I.	II.			
	h. m.	h. m.	° ′	° ′		° ′	′
December 21	22 24	− 1 57	336 15	157 4	E.	113 28	+ 2
	23 16	− 1 4	336 5:	156 57	E.	113 37	+ 11
December 22	1 0	+ 0 39	335 52	156 44	E.	113 50	+ 24
	1 5	+ 0 44	203 30	24 23	W.	113 49	+ 23
	3 2	+ 2 41	335 47	156 41	E.	113 54	+ 28

From these five observations it is concluded that the pole of the instrument was directed to a point 18′ below and 25′ east from the pole of the heavens.

Rigorously the preceding observations suffice for the complete determination of the angle which the line of motion of the instrument in declination makes with the meridian at any point. But, to have a check on the correctness of the results, several transits of pairs of stars, near in R. A. but more distant in declination, were observed over the middle wire of the telescope, the pointing of the latter in R. A. remaining unchanged

between the transits of each pair. These observations were made on the night preceding the eclipse, and are as follows:

	Chronometer. h.	m.	s.
Transit of β Ceti over middle wire	7	41	31
Transit of ε Piscium, telescope being moved in declination only	8	0	19.5
Difference of mean times of transit		18	48.5
Difference of sidereal times of transit		18	51.5
Difference of right ascensions of stars		19	8.4
Amount by which the southern star passes too late			16.9
Transit of γ Geminorum	10	9	18.5
Transit of Sirius	10	19	6.0
Difference of right ascensions		9	12.4
Southern star too late			36.6
Transit of α Andromedæ	10	27	42.5
Transit of γ Pegasi	10	32	14.0
Difference of right ascensions		4	52.3
Southern star too early			20.0
Transit of α Andromedæ	10	35	17
Transit of γ Pegasi	10	39	47
Southern star too early			21.5

NOTES.

1. The two wires are discordant by 30^s, and the observation is not used.

9. Before this observation the transit wires were found far from vertical, though they had been carefully adjusted on the 17th. They were readjusted, and, on examining the collimation by reversal on a distant object, the middle wire was found too near the clamp side of the instrument by an amount estimated at $0^s.10$ or $0^s.12$.

8, 19. Before each of these observations the azimuth was accidentally changed by moving the azimuth-screw.

Station to determine the error of the Chronometer on Local Time.

NOTES.

22. On the following morning the collimation was examined by reversal, and the middle wire found too near the clamp end of the axis by $0^{r}.031$ of the azimuth-screw. The observation was made in sunshine. The results for chronometer error seem to show that this collimation is fictitious; but, as the error will be eliminated from the mean of observations made in both positions of the instrument, I have made no change in the result.

H.

Determination of Constants pertaining to the Transit-Instrument.

Calling wire I that nearest the clamp end of the axis, the eight transits observed over both wires, I and IV, were taken, and the observed intervals separately reduced to the equator by multiplying them by cos δ. The same thing was done with the ten transits observed over wires IV and VII. The results were:

$$\begin{aligned} & \qquad\quad \mathrm{s.} \\ \mathrm{VII}-\mathrm{IV} &= 63.28 \\ \mathrm{IV}-\mathrm{I} &= 63.34 \\ \mathrm{VII}-\mathrm{I} &= 126.62 \end{aligned}$$

The intermediate wires were determined by means ot the azimuth-screw of the instrument. The latter being pointed on a distant mark, the readings of the screw for coincidence of the several wires with the mark were as follows:

Wires.	Microm.	Intervals.	Intervals in time.	Reduction of each wire to IV.
	r.	r.	s.	s.
I.	20.806	1.620	21.56	+ 63.54
II.	19.186	1.590	21.17	+ 41.98
III.	17.596	1.563	20.81	+ 20.81
IV.	16.033	1.627	21.67	0.00
V.	14.406	1.584	21.09	− 21.67
VI.	12.822	1.528	20.34	− 42.76
VII.	11.294			− 63.10

From the first and last of these readings is concluded:

$$\begin{aligned} \mathrm{VII}-\mathrm{I} &= 9^{\mathrm{r}}.512 = 126^{\mathrm{s}}.62 \\ 1^{\mathrm{r}} &= 13^{\mathrm{s}}.312 \end{aligned}$$

and the intervals and reductions to middle wire are thence deduced.

To find the value of one revolution of the level-screw, the instrument was fastened in its Y's by an elastic cord, and the stand was then tipped over so that the level-screw was horizontal. The following three intervals were then determined in the same way with that employed in investigating the azimuth screw:

$$\begin{aligned} \mathrm{II}-\mathrm{I} &= 1^{\mathrm{r}}.590;\ \text{difference from azimuth screw} = -0^{\mathrm{r}}.030 \\ \mathrm{III}-\mathrm{II} &= 1^{\mathrm{r}}.569;\ \text{difference from azimuth screw} = -0^{\mathrm{r}}.021 \\ \mathrm{IV}-\mathrm{III} &= 1^{\mathrm{r}}.521;\ \text{difference from azimuth screw} = -0^{\mathrm{r}}.042 \end{aligned}$$

From this is concluded,

$$\begin{aligned} 4^{\mathrm{r}}.680 &= 63^{\mathrm{s}}.54 \\ 1^{\mathrm{r}} &= 13^{\mathrm{s}}.58 \end{aligned}$$

The Spirit-Levels.

These were put upon the axis of the instrument in succession, and their bubbles were read in different positions of the level-screw, as follows:

Level screw.	Level B.		Level screw.	Level A.	
	W.	E.		W.	E.
r.	*d.*	*d.*	*r.*	*d.*	*d.*
.109	28.0	77.0	.235	55.5	82.0
.210	45.5	58.5	.350	79.0	57.8
.300	60.0	43.0	.250	56.0	80.0
.100	20.0	83.5	.370	81.5	55.0
.300	57.0	45.5	.240	51.5	84.0
.400	74.0	28.0	.400	85.5	49.5
.100	15.0	88.0			

Having regard to the value just found for one revolution of the level-screw, it is concluded that

One division of level A $= 0^s.065$
One division of level B $= 0^s.072$

I.

Exchange of Signals with Professor Hall at Malta, through the Falmouth, Gibraltar and Malta Cable.

DECEMBER 15.

A signal was sent every fifteen seconds from $4^h\ 45^m\ 0^s$ to $4^h\ 50^m\ 0^s$, chronometer time, but the signal which should have been sent at $4^h\ 49^m\ 45^s$ was half a second late.

Signals from Malta were received at the following times:

h.	m.	s.	h.	m.	s.
4	52	47.1	4	55	2.2
	53	2.4			17.3
		17.4			32.4
		32.4			47.3
		47.3		56	2.5
	54	2.5			17.3
		17.3			32.2
		32.3			47.4
		47.3		57	2.4
					17.4

Next morning, December 16, civil time, signals were sent to Malta every fifteen seconds from $23^h\ 32^m\ 0^s$ to $23^h\ 37^m\ 0^s$.

Signals from Malta were received as follows:

h.	m.	s.	h.	m.	s.
23	39	18.7:	23	42	3.2
		32.7:			18.0
		48.0:			33.0
	40	3.0			48.1
		17.9:		43	3.2
		33.0			18.3
		48.1			33.2
	41	3.2			48.1
		18.2		44	3.0
		33.2			18.3
		48.1			

NOTE.—The signals were sent by pressing a key simultaneously with the proper beat of the chronometer. They were received by having an operator strike a key as soon as he saw the motion of the image reflected from the mirror of the galvanometer. The time of this stroke was noted by the observer at the chronometer.

REPORT

OF

PROFESSOR ASAPH HALL, U. S. N.

REPORT OF PROFESSOR HALL, U. S. N.

UNITED STATES NAVAL OBSERVATORY, *Washington, February* 27, 1871.

SIR: I have the honor to submit the following report of my observations of the solar eclipse of December 22, 1870.

I left New York November 2, on the Cunard steamship China, and, arriving at Liverpool November 13, proceeded thence by the way of London to Southampton, and from that port by the steamship Poonah, of the Peninsular and Oriental Line, to Malta, and from Malta by the Florio steamer to Syracuse; arriving at Syracuse December 8. I returned to Malta December 12, and remained there four days for the purpose of exchanging telegraphic signals for longitude with Professor Newcomb at Gibraltar, and with Professor Harkness at Syracuse.

We left Syracuse the day after the eclipse, and, passing through Italy and Central Europe, I returned to England by the way of Ostend and Dover. Leaving Liverpool January 21, I arrived at Washington February 3, 1871.

I wish to express my sincere thanks to Signor Nunzio Stella, the American consular agent, and to the civil and military authorities of Syracuse, for their kind attentions to our party, and for the facilities afforded us. I am indebted also to Signor Bisani, the English consular agent, for his assistance.

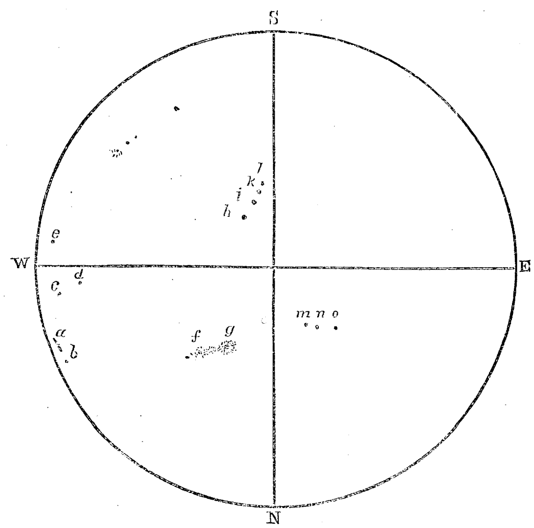
At Malta I was under great obligations to Mr. Lyell T. Adams, our consul, and to Mr. B. Smith and Mr. Edward Rosenbusch, superintendents of the telegraph offices in Malta. It was only through the energy and skill of Mr. Rosenbusch that we were able to make the telegraphic connections between Malta and Syracuse. I have to offer my thanks to Messrs. Pisani, Portelli, Fauqueir, and other gentlemen connected with the telegraph offices, for the assistance rendered me in exchanging the signals. To Mr. Pisani I am also indebted for assistance in my time observations. I am under special obligations to Captain G. L. Tupman, of the Royal Marine Artillery, who assisted me in many of my sextant observations, and who furnished me with much local information. M. Berthet, optician at Valetta, very kindly allowed me the use of his fine transit-instrument. The whole party is much indebted to the Messrs. Negus, of New York, who furnished us with excellent chronometers.

THE ECLIPSE.

My observing station in Syracuse was on the "Bastione San Filippo," a little north of the gate "Prima Porta Terra." My telescope was a comet-seeker by Ploessl, with a 3¾-inch object-glass and a magnifying power of about fifty. The following are my observations of the times of contact and the bisections of solar spots. The times observed are those of the chronometer Negus 1228, and were observed with a dark glass at the eye-piece except those of the second and third contacts, or the beginning and end of total eclipse, which were observed without the shade:

Object.	Ch. Negus 1228.	Chron. corr.	Local M. T.	Notes.
	h. m. s.	h. m. s.	h. m. s.	
First contact . . .	11 37 35.0	+ 1 0 38.0	0 38 13.0	Fair.
Spot *d*	11 43 16.0	1 0 38.0	0 43 54.0	Fair.
Spot *f*	0 0 51.0	1 0 38.0	1 1 29.0	Fair.
Spot *h*	0 12 6.0	1 0 38.0	1 12 44.0	Good.
Spot *m*	0 33 27.0	1 0 38.0	1 34 5.0	Good.
Spot *n*	0 34 46.0	1 0 38.0	1 35 24.0	Good.
Spot o_1	0 37 37.0	1 0 38.0	1 38 15.0	Fair.
Spot o_2	0 38 5.0	1 0 38.0	1 38 43.0	Fair.
Second contact . .	1 2 17.5	1 0 38.0	2 2 55.5	Good.
Third contact . . .	1 4 0.0	1 0 38.0	2 4 38.0	Poor.
Fourth contact . .	2 21 20.5	+ 1 0 38.0	3 21 58.5	Fair.

The annexed diagram of the solar spots was made about an hour before the beginning of the eclipse, and will serve to identify the spots observed. The observed times of contact agree very closely with those computed from the data of the American Ephemeris, the longitude of Syracuse being assumed as $-6^h\ 9^m\ 25^s.6$; but as our attempt to determine the longitude of Syracuse from Greenwich was unsuccessful, on account of a break in the submarine cable between Gibraltar and England, no accurate comparison with the tables can be made. Assuming, however, that the longitude of Gibraltar is tolerably well known, our telegraphic connection with that point enables us to determine the longitude of our observing station at Syracuse. In this way Professor Harkness finds for the longitude east of Washington



$$6^h\ 9^m\ 27^s.8$$

By combining the results of all the sextant observations, Professor Harkness has deduced as the most probable value of the latitude of our station

$$\varphi = +\ 37°\ 3'\ 52''.6 \pm 2''.98$$

I have adopted therefore.

$$\varphi = +\ 37°\ 3'\ 53''$$
$$\lambda = -\ 6^h\ 9^m\ 27^s.8$$

and a computation from the data of the American Ephemeris gives the following times of contact:

Phase.	Computed times.			Observed times.			$\Delta t.$
	h.	m.	s.	h.	m.	s.	s.
First contact . . .	0	38	19.2	0	38	13.0	+ 6.2
Second contact . .	2	3	5.1	2	2	55.5	+ 9.6
Third contact . . .	2	4	46.1	2	4	38.0	+ 8.1
Fourth contact . .	3	22	8.0	3	21	58.5	+ 9.5

The following differential equations will serve for computing changes in the times of contact produced by small changes in the position of the observing station:

$$dt = -\ 0.014\ d\varphi - 1.525\ d\lambda,\ \text{first contact,}$$
$$dt = -\ 0.014\ d\varphi - 1.509\ d\lambda,\ \text{second contact,}$$
$$dt = -\ 0.014\ d\varphi - 1.423\ d\lambda,\ \text{third contact,}$$
$$dt = -\ 0.014\ d\varphi - 1.300\ d\lambda,\ \text{fourth contact,}$$

$d\varphi$ being expressed in seconds of arc, and $d\lambda$ in seconds of time. The value of φ is supposed to increase positively toward the north and that of λ toward the west.

The times of contact computed by Signor Agnello, of the Palermo Obervatory, are on an average 25 seconds earlier than those which I have computed, except the time of first contact, which is 88 seconds later, evidently a misprint or the result of some error of computation. Signor Agnello's data is that of the English Nautical Almanac.

My chief purpose during the total eclipse was to observe the structure of the corona, with special reference to the curved and radiating lines seen in previous eclipses, but the condition of the sky was such that this observation was unsatisfactory. During the last quarter of an hour of the first partial phase it appeared hopeless that the total eclipse would be visible, the sun being covered by a thick cloud. This cloud, however, had a slow motion upward and toward the east, and a few minutes before totality the nar-

row crescent of the sun appeared through the clouds. On account of these clouds I was able to take off my colored glass shade and watch the disappearance of the sun without any protection or inconvenience to the eye. The apparent diameters of the sun and moon being nearly equal, the bright crescent became extremely long and narrow, and broke up into bits and fragments, but I noticed no color nor anything remarkable before the disappearance of the last long, thin remnant. After recording my observed time of the beginning of total eclipse I pointed the telescope to the east limb of the moon and swept around toward the south back to the starting point. I should not estimate the extent of the corona to be more than five or ten minutes from the limb of the moon, but the clouds make this estimate quite uncertain; and with regard to the form or outline of the corona it could not, I think, be observed with accuracy. The appearance of the corona in the telescope was that of a soft, white, diffused light. There was very little appearance of the radiating lines shown in many pictures, and I saw no curved streamers. Near the southwestern point of the moon there was apparently a deep opening in the corona, reaching nearly to the limb of the moon, but on account of the clouds this opening was very indistinct.

After sweeping around the moon I pointed the telescope on one of the large protuberances near the eastern limb of the moon, but could see nothing of the spotted or cellular appearance seen by Professor William A. Rogers in the eclipse of August 7, 1869. The protuberances, which were very numerous, were uniformly of a dull pink color. Then having some fifteen or twenty seconds to spare, I looked at the eclipse with the naked eye. The moon was still covered with the light and shifting clouds, but as they were rising and passing toward the east the lower and southwestern part of the moon was much the clearer. At this point the corona was quite bright, and here several delicate streamers shot down to the distance of eight or ten degrees. There was no color, and to the naked eye the corona appeared, as in the telescope, of a soft, white light. Putting my eye back to the telescope I observed the first reappearance of the sun through a deep notch in the moon's limb. This a little disturbed me and made my observation of the end of totality somewhat uncertain.

The darkness during total eclipse was much less than during the eclipse of August, 1869. As the totality approached it became quite cold, and a strong wind arose, but as my telescope had a solid, firm mounting, the wind gave me no trouble. I did not see the planet Saturn, which was a little north of the moon, but my attention was not specially directed to the discovery of the planet.

The general appearance of the total eclipse was something as follows: The black moon in the center surrounded with a narrow rim of bright light a quarter or half a minute in thickness. Above this rim rose the dull pink-colored protuberances, and beyond these extended the white corona, the whole making a very beautiful sight. I refrain from attempting to make any picture of the eclipse. On account of the suddenness, the beauty and grandeur of the phenomena displayed, it is very difficult to make a correct picture by hand-sketching; and so much must the memory be relied on, and so great is the opportunity for the play of the imagination, that I can have but little faith in such pictures. Photography appears to furnish the only means of making a truthful picture. At Syracuse we were fortunate in having the companionship of three English observers, Messrs. Brothers and Fryer, of Manchester, and Mr. Griffith, of Harrow. Messrs. Brothers and Fryer obtained several photographs of the total eclipse, and one which was understood to be very satisfactory.

At the instant of the beginning of total eclipse I noticed in the telescope an appearance that it may be worth while to describe. The protuberances darted quickly into view, and there was a flashing back of the sunlight, and an apparent mingling of red and white light that was very striking. The appearance was somewhat like that given by Mr. Gilman in his picture of the eclipse of 1869, but it was, I think, an optical illusion, for after recording my time and putting my eye again to the telescope the appearance was entirely gone.

With regard to the long streamers seen near the end of totality, I had the impression when seeing them that they were not of the corona proper, but were produced in the earth's atmosphere. This impression was caused, perhaps, by the proximity of the clouds, and by the resemblance of the streamers to the phenomenon commonly spoken of as the "sun's drawing water," only the streamers were much more delicate and more like what we see sometimes in our atmosphere on a hazy day.

SEXTANT OBSERVATIONS.

I give below the observations for time and latitude made at Malta and Syracuse with the Pistor & Martins patent sextant No. 107. The altitudes were observed by myself, and the times at Malta by Captain Tupman and Mr. Pisani; at Syracuse by Professor Eastman, Captain Tupman, and myself. In the column of dates I have placed the initials of the observers. It should be stated that the observations at Malta, until December 15, were made with the low power, as the colored shade had become so firmly fixed to this telescope during the transportation of the instruments that I did not succeed in removing it until the evening of December 14.

If we consider the spherical triangle formed by the star, the zenith of the observer, and the pole of the heavens, and designate by h, δ, t, the altitude, the declination, and hour angle of the star, we shall have the equation,

$$\sin h = \sin \varphi \sin \delta + \cos \varphi \cos \delta \cos t$$

Since sextant observations for time should be made as near the prime-vertical as practicable, the hour angle will be accurately determined by means of its cosine, and the above simple formula is, I think, more convenient for computation, and more exact than the transformed expressions that are usually employed. For the reduction of the latitude observations I have used the following formula derived from the preceding one by an easy transformation:

$$\cos (\varphi - \delta) = \sin h + 2 \cos \varphi \cos \delta \sin \tfrac{1}{2} t^2$$

If we differentiate the first equation, considering δ constant and denoting by A the azimuth, we shall have,

$$dt = -\frac{dh}{\cos \varphi \sin A} - \frac{d\varphi}{\cos \varphi \tan A}$$

This differential equation shows the importance of making the observations for time symmetrical with respect to the meridian. It has been computed for the mean hour angle in each set of observations, dt being expressed in seconds of time, and dh and $d\varphi$ in seconds of arc.

At Malta my observing station was at the telegraph office except on the first day, December 13, when the observations were made at Spencer's Monument. According to the map of the Ordnance Survey of Malta, Spencer's Monument is 253 yards west and 2,013 yards south of the telegraph office. In reducing the observations made at Syracuse the latitude was assumed to be $+37° 3'.5$, and a reduction, Δt, to the latitude finally adopted, is given in the column of results.

The following are the values of the latitudes obtained from the sextant observations:

		°	′	″	
Malta, Spencer's monument,	$\varphi = +$	35	52	55;	16 altitudes of the sun.
Malta, telegraph office,	$\varphi = +$	35	54	11;	20 altitudes of the sun.
Syracuse, Bastione San Filippo,	$\varphi = +$	37	3	57;	12 altitudes of the sun.
Syracuse, Bastione San Filippo,			3	61;	16 altitudes of the sun.
Syracuse, Bastione San Filippo,			3	61;	16 altitudes of the sun.
Syracuse, Bastione San Filippo,			3	39;	12 altitudes of Polaris.
Syracuse, Bastione San Filippo,			3	31;	8 altitudes of Polaris.
Mean latitude,	$\varphi = +$	37	3	48

When at Malta I was permitted by M. Berthet to use his transit-instrument. This instrument, made by Secretan, of Paris, in 1862, has an objective of three inches, and is very well mounted in an observatory on St. James Cavalier, the meridian of which differs but little from that of the telegraph office. As the value of the level divisions had not been determined, the level, and also the collimation error, were made zero by M. Berthet a short time before the observations. The wires of the instrument were too thick to admit of very accurate observations of transits, but the following may serve as a check on the determinations of time with the sextant:

TELEGRAPHIC SIGNALS FOR LONGITUDE.

Through the kindness of Mr. Rosenbusch the telegraph offices at Malta and Syracuse were furnished with small portable and very convenient instruments for sending and receiving the signals. Each instrument was provided with two keys, worked by the observers, and the signals were given by the observer striking his key in coincidence with the beat of his chronometer. The signals were recorded on a fillet of paper similar to that used with the Morse register. For example, the observer at Syracuse gave signals every fifth second of his chronometer for three minutes, the observer at Malta during the same time giving signals at every second of his chronometer, and, both sets of signals being recorded on the fillet of the Malta instrument, a very accurate comparison of the chronometers was obtained. The operation was then reversed, the observer at Malta sending signals every fifth second to Syracuse, and the chronometers were compared on the fillet of the Syracuse instrument. The following are the results of the readings of the fillets. At Syracuse the signals were made by Professor Harkness, who used the chronometer Negus 1115. At Malta I used the chronometer Negus 1228.

Date.	Malta fillet. Ch. 1228—Ch. 1115	Syracuse fillet. Ch. 1228—Ch. 1115
1870. h.	m. s.	m. s.
Dec. 13, 0.4	+ 2 4.22	+ 2 4.23
14, 3.3	+ 2 4.44	+ 2 4.47
15, 3.5	+ 2 4.79	+ 2 4.80
16, 1.1	+ 2 5.25	+ 2 5.23

If we denote by c and c' the chronometer times when the signal was sent and received, and by Δc and $\Delta c'$ the corrections of the chronometers, the difference of longitude will be,

$$c - c' + \Delta c - \Delta c' + \varepsilon$$

where ε is the time required for the signal to pass from one station to the other. The present observations do not furnish data for the determination of ε, and its further consideration is omitted. The preceding table gives the values of $c-c'$, and Professor Harkness has furnished the corrections of the chronometer Negus 1115. Collecting the necessary quantities, we have the following results for the difference of longitude between the telegraph office in Malta and our station in Syracuse:

Date.	Corr. ch. 1228.	Corr. ch. 1115.	$c-c'$	$\Delta\lambda$
1870.	h. m. s.	h. m. s.	m. s.	m. s.
December 13	+ 0 57 28.3	+ 1 2 43.2	+ 2 4.2	— 3 10.7
14	+ 0 57 28.5	+ 1 2 44.0	+ 2 4.4	— 3 11.1
15	+ 0 57 28.7	+ 1 2 44.4	+ 2 4.8	— 3 10.9
16	+ 0 57 29.2	+ 1 2 44.7	+ 2 5.2	— 3 10.3

Taking the mean of these results, we have Syracuse east of Malta

$$3^{m}\ 10^{s}.7 \pm 0^{s}.33$$

Omitting all consideration of personal equation in sending the signals, the comparison of the chronometers by means of the telegraph may be considered as exact, since from 164 comparisons it results that the probable error of a single comparison is only $\pm 0^{s}.034$. From the 240 altitudes observed, I find that the prob-

able error of one of my time determinations from the mean of 12 altitudes is $\pm 0^s.27$. On the other hand, the sun was observed at azimuths of about forty degrees only east and west of the meridian, and the differential equations show that an error of $10''$ in the altitude will produce an error of more than one second in the time. From these considerations I estimate the probable error in the difference of longitude to be one-third of a second.

The following is the record of the signals exchanged with Professor Newcomb, who was at Gibraltar. In sending the signals, the observer struck the telegraph key in coincidence with the beat of his chronometer. The signals were received in the following manner: A telegraph-operator watched the bright image of the mirror, and at the instant he observed a motion of the image he struck a key that gave a sharp click, and the time of this click was observed on the chronometer at Gibraltar by Professor Newcomb, and at Malta by myself.

Mean, (21,) $0^m\ 16^s.95 \pm 0^s.004$ Mean, (17,) $0^m\ 18^s.13 \pm 0^s.005$

Hence collecting the quantities and using the corrections of chronometer 1265 found by Professor Newcomb, we have the following results:

Date.	Corr. chron. 1228.	Corr. chron. 1265.	$c-c'$	$\Delta\lambda$
1870.	h. m. s.	h. m. s.	m. s.	h. m. s.
Dec. 15	+ 0 57 28.7	— 0 22 16.5	— 0 16.8	- 19 28.4
16	+ 0 57 29.2	— 0 22 15.3	— 0 17.5	1 19 27.0

The determination of time at Gibraltar, on December 16, is from an observation of α Lyræ, while the determination of the 15th is from four observations east and west of the meridian, and is therefore much more trustworthy. I adopt, as the difference of longitude,

$$1^h\ 19^m\ 28^s.4 \pm 0^s.5$$

If we reject the time determination of December 16 at Gibraltar, and assume a constant rate of the chronometer from the 15th to the 19th, the resulting longitude for the 16th will be $1^h\ 19^m\ 28^s.5$; but this process does not, I think, add any weight to the adopted value.

As indicated by the date, the principal part of the preceding report was written immediately after my return home and before I had seen any reports or discussions of the observations in Sicily. A small part of the numerical reductions could not be completed until I had received from Professors Newcomb and Harkness their determinations of local time.

Very respectfully, your obedient servant,

ASAPH HALL,
Professor of Mathematics, U. S. N.

Commodore B. F. SANDS, U. S. N.,
Superintendent U. S. Naval Observatory, Washington, D. C.

REPORT

OF

PROFESSOR WM. HARKNESS, U. S. N.

REPORT OF PROFESSOR WM. HARKNESS, U. S. N.

UNITED STATES NAVAL OBSERVATORY,
Washington, July 13, 1871.

SIR: In accordance with orders from the Navy Department, dated September 16, 1870, I have the honor to submit to you the following report in relation to the astronomical and other observations made by me in connection with the expedition sent to Sicily, by this Observatory, for the purpose of observing the total solar eclipse of the 22d of December last.

I.—INTRODUCTORY.

I left Washington at 9 p. m., October 28, arriving in New York early the following morning. The next three days were spent in arranging details regarding the transportation of the officers and instruments of the party, and at 2 p. m., November 2, Professors Hall, Eastman, and I, sailed from Jersey City in the Cunard steamer China. After an unusually rough and disagreeable passage we arrived safely in Liverpool at 12.30 p. m., November 13. We had with us no less than ten cases of instruments, all of which were most courteously passed through the custom-house without being opened, and without a moment's delay, the authorities saying that they had received orders from the government at London to do so. At 4.45 p. m., November 15, Mr. Alvan Clark, jr., and I, left Liverpool by rail for York, where we spent the night. The next morning we visited the works of Messrs. T. Cooke & Sons, and in the afternoon, by appointment, we met Professor Newcomb at the railway station, and went on with him to Newcastle, and thence to Gateshead, for the purpose of seeing Mr. Newall's gigantic refracting telescope.

While on the train, Professor Newcomb told me that he had selected Gibraltar as the most suitable station from which to make his observations on the eclipse, and that he had made all necessary arrangements with the Astronomer Royal, and with the various telegraph companies whose wires would be required, to exchange longitude signals between Greenwich and that place. He also added that he had informed the managing directors of the submarine cables that it was probable I would be desirous of determining the difference of longitude between Gibraltar and my station at Syracuse, and that they had expressed their entire willingness to grant me the free use of their wires for that purpose if I would make known my wishes to them. Accordingly, when I subsequently passed through London, on my way to Southampton, I called on W. T. Ansell, esq., secretary of the Falmouth, Gibraltar, and Malta Telegraph Company, and he introduced me to Sir James Anderson, managing director of that company, and also of the Anglo-Mediterranean Telegraph Company. These gentlemen treated me with the greatest kindness, evincing a deep interest in our scientific operations, and showing a very strong desire to do all in their power to insure our success. They at once granted me the free use of their cables for the exchange of longitude signals, and furnished me with a letter of introduction to Benjamin Smith, esq., their superintendent at Malta, requesting him to afford me every possible facility. In addition, Sir James Anderson wrote a note to Edward Tombs, esq., secretary of the Mediterranean Extension Telegraph Company, who own the submarine cable between Malta and Sicily, requesting him to grant me the free use of their line, and to furnish me with a letter of introduction to Edward Rosenbusch, esq., their engineer and general superintendent at Malta. This was at once done, and I here desire to offer my thanks to all the above-named gentlemen for their liberality in the cause of science.

At 3 p. m., November 26, our party sailed from Southampton on the Peninsular and Oriental Company's steamer Poonah. During the voyage we touched at Lisbon and Gibraltar, and, after a tolerably pleasant passage, we landed at Malta about 12.30 a. m., December 6. A day or two before arriving at the last mentioned place I became slightly acquainted with one of my fellow passengers, who manifested some interest in our expedition, and who, upon learning that we contemplated using the telegraph cables for longitude purposes, said that he was a director in the company, and that when we got to Malta he would go

on shore and request their superintendent to afford me all possible assistance. He fulfilled his promise at the expense of no little personal inconvenience, for the Poonah reached Malta about half an hour after midnight and departed about daylight the following morning. While on board ship I was ignorant of the gentleman's name, but the superintendent at Malta subsequently told me that it was Mr. Elliot, of the well-known firm of Glass, Elliot & Co., and I here desire to offer him my thanks for his kind interest in the welfare of our expedition.

For the better understanding of what follows, it may be well to give some details as to the ownership and management of the telegraph lines which we proposed to use in determining differences of longitude. The land lines from the Greenwich Observatory to Porthcurno are owned and controlled by the English government, R. S. Culley, esq., being the engineer-in-chief. The submarine cables from Porthcurno to Lisbon, from Lisbon to Gibraltar, and from Gibraltar to Malta, are owned and controlled by the Falmouth, Gibraltar, and Malta Telegraph Company, Sir James Anderson, managing director, Benjamin Smith, esq., superintendent at Malta. The submarine cable from Malta to Modica, in Sicily, is owned and controlled by the Mediterranean Extension Telegraph Company, Edward Tombs, esq., secretary, Edward Rosenbusch, esq., engineer and general superintendent, residing at Malta. The land lines from Modica to Florence are owned by the Italian government, but one of the wires is leased to and controlled and worked by the Anglo-Mediterranean Telegraph Company, Sir James Anderson, managing director, Edward Rosenbusch, esq., engineer and general superintendent. Syracuse is on the line from Modica to Florence. It will thus be seen that in working from Malta to Syracuse we would be using the wires of two different companies, but, as Mr. Rosenbusch is engineer and general superintendent of both, the whole line is under the control of one man.

On the morning of December 6 I made inquiries as to where the offices of the various telegraph companies were to be found in Malta, and was told that they were all in the same building. I also learned that Mr. Smith, local superintendent of the Falmouth, Gibraltar, and Malta line, boarded at Dunsford's Hotel, where I was then staying. Accordingly, I called on him in his room, and presented my letter of introduction. He received me very kindly, and took me to the telegraph office, where, after showing me everything, he placed a clerk and a complete set of the company's apparatus at my disposal, in order that I might become quite familiar with it, as it was very different from the apparatus employed in the American telegraph offices. He assured me that there would not be the least difficulty in exchanging signals between Malta and Gibraltar, and that the only thing necessary was for me to designate what apparatus I wished used and how I would have it handled during the longitude work. This I did, and I have to thank him, and the gentlemen attached to his staff, for their very efficient assistance in carrying out our operations.

I next called on Mr. Rosenbusch, engineer and general superintendent of the Mediterranean Extension Telegraph Company, and of the Anglo-Mediterranean Telegraph Company—a gentleman whom I subsequently learned to know as one of the kindest and best friends that it was my good fortune to meet during my absence abroad. He told me that, so far as the Malta end of the line was concerned, there would not be any difficulty, for he was ready to do anything that I might deem necessary; but that at Syracuse the case was different, because the wire controlled by his company is a through one, and their contract with the Italian government only permits them to have offices at Modica and Florence. Hence, as all telegraph offices in Italy are controlled by the government, it would be necessary to secure its assent before it would be possible for us to use the company's wire between Modica and Syracuse. In order to procure this assent, Mr. Rosenbusch at once telegraphed to Florence to Commendatore Ernest d'Amico, director general of the Royal Italian telegraph lines, and in twenty-four hours I had the satisfaction of learning that Signor Emmanuele Astor, sub-inspector of the Royal Italian telegraphs, had been ordered to proceed to the telegraph office at Syracuse, and there to give us every possible facility for exchanging longitude signals with Malta. Moreover, as Signor Astor and the other telegraph officials whom I would meet at Syracuse spoke only Italian, a language of which I know very little, Mr. Rosenbusch kindly volunteered to accompany me to overcome all difficulties that might arise on that score, and to give me the benefit of his influence with various government officers at Syracuse, all of whom were his personal friends.

I was now ready to proceed to Syracuse, but, as the steamer was not advertised to sail until Friday evening, I amused myself during the interval of waiting by visiting the various objects of interest in and around Malta. And here I must not omit to mention that my pleasure in so doing was greatly enhanced by numerous kind attentions shown me by our consul, Lyell T. Adams, esq., and our vice-consul, William John Stevens, esq.

The Malta channel is often very rough, and at such times the small steamers of the Florio line, which carry the mails between Malta and Sicily, do not venture to cross. Unfortunately for us, Wednesday, Thursday, and Friday were quite stormy, and when we went to bed on Saturday night the steamer had not yet arrived.* At 6 o'clock on Sunday morning, December 11, I was awakened by the joyful tidings that the mail-steamer had just come in, and that she would depart for Syracuse as soon as her freight could be got on shore. I dressed rapidly, but there was much delay in getting breakfast, and I was afraid the steamer would be off without us. The fear was groundless. I, in company with Professor Eastman and Mr. Rosenbusch, was on board at 9 o'clock, and she did not sail till a quarter before 11. She was the Corriére Siciliano—a nice little boat—and after a very pleasant passage of about eight hours, she landed us in Syracuse at 7 o'clock in the evening. Professor Hall, in company with Dr. C. H. F. Peters, of the United States Coast Survey Eclipse Expedition, had gone over to Sicily on December 6, and had secured on our behalf the kind offices of our consular agent, N. Stella, esq., and of the English consul, Nicolo Bisani, esq. These gentlemen met us at the custom-house, and, thanks to them and to Mr. Rosenbusch, our personal baggage was passed without being opened, and we went at once to the Albergo della Vittoria, where we were furnished with pleasant quarters, and made very comfortable during our stay in Syracuse.

About 8 o'clock the same evening Mr. Rosenbusch and I visited the telegraph office in Syracuse, where we met Signor Emmanuele Astor, sub-inspector of Royal Italian telegraphs, Signor Raffaele Spagna, superintendent of the Syracuse office, and Signor Mario Lanza, assistant in the Syracuse office. We found these gentlemen willing to do everything in their power for us, and after a little consultation all the details relative to the exchange of longitude signals were satisfactorily arranged.

At 12.30 p. m., December 12, Professor Eastman, Mr. Rosenbusch, and I, made an official visit to Chevalier Achille Basile, royal prefect of the province of Syracuse, who received us most kindly, and said that it would afford him the greatest pleasure to be of service to us while we remained in Syracuse. That same afternoon he had the boxes containing our instruments passed through the custom-house without being opened, and delivered to us at our hotel.

II.—SITE OF OBSERVING-STATION.

After making a thorough reconnaissance of the whole city of Syracuse, the place which seemed to me best adapted for our observing-station was the bastion situated on the north side of the Prima Porta Terra. The surface of the ground there was 52 feet above the sea-level, and, with the exception of an arc of 55°, included between the true bearings S. 5° W. and S. 50° E., the horizon was perfectly unobstructed. The obstructions in the arc in question consisted of the buildings in the more elevated part of the city, but they nowhere rose so high as to interfere with astronomical observations.

I accordingly wrote a note to the Prefect, requesting to be permitted to occupy the bastion as our observing-station, and asking for the loan of two tents to shelter our instruments. He replied that the bastion was at our service, and, if we wished, he would also give us the use of a large empty store-house in it. As our instruments were all so portable that it was not necessary to leave them in position during the night, the store-house was much better adapted to our wants than tents would have been, and I gladly accepted it. At 9 a. m., December 13, the Prefect sent an officer of his staff to take us to the bastion, to put us in possession of the store-house, and to inform us that he would have a military guard detailed, whose duty it would be to see that no injury came to our property. That same morning we had our boxes sent from the hotel to the store-house, got our instruments unpacked, and began observing. During the forenoon the guard arrived, and from that time till we left Syracuse there was always a sentinel at the door of the store-house.

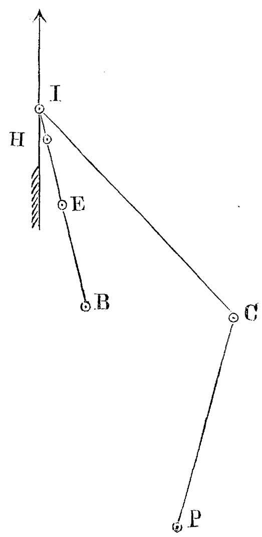
On the evening of December 16, Messrs. A. Brothers and Alfred Fryer, of the English Eclipse Expedition, arrived in Syracuse; and on the morning of December 21, Mr. George Griffith, also of the English expedition, arrived. By our invitation, and with the consent of the Prefect, these gentlemen occupied the bastion and store-house in common with us as an observing-station.

---

* There are often very great delays, occasioned by rough weather, in getting from Malta to Sicily, and as there was every appearance that we were to be the victims of one of them, at a time when it was very important that we should get speedily to Syracuse, in order to determine our longitude, on Friday Vice-Admiral Sir Hastings Reginald Yelverton, K. C. B., commander-in-chief of H. B. M. Mediterranean squadron, sent a message to us through our consul, saying that if the mail-steamer did not arrive by Monday, he would on that day send us to Syracuse in his own dispatch-vessel, the Psyche. Such generosity should not be passed over in silence, and it gives me pleasure to offer the thanks of the party to Vice-Admiral Yelverton.

Figure 1, drawn on a scale of 1 to 2500, shows the exact positions occupied by the instruments of the different observers in the bastion. The point P is directly over the key-stone in the east, or city, face of the arch over the Prima Porta Terra. 1 is a stone gun-platform, which was situated near the northern end of the western face of the bastion. On it were made the observations for time and latitude, and on the day of the eclipse Professor Hall's telescope stood upon it. H and E indicate, respectively, the position of my telescope and of that of Professor Eastman. B is the position of Mr. Brothers's photographic telescope. Mr. Griffith's telescope stood between E and B. The following are the measured distances, corrected for error in length of tape-line:

Fig. 1.



1 to C = 316.2 feet = 96.38 meters.
C to P = 236.4 feet = 72.05 meters.

1 to H = 34 feet = 10.4 meters.
1 to E = 110 feet = 33.5 meters.
1 to B = 226 feet = 68.9 meters.

The angles at 1 were

B and Belvedere Tower = 125° C and Belvedere Tower = 154° 35′

Angle 1 C P = 121° 30′

Hence I find

Distance from 1 to P = 483.8 feet = 147.5 meters.

Angle C 1 P = 24° 37′ 35″ Angle C P 1 = 33° 52′ 25″

The true bearing from 1 to the Belvedere Tower was N. 68° 23′ 28″ W. Combining this with the angles given above, I find for the true bearing from 1 to P, S. 18° 20′ 53″ E.

The instruments were used in the open air, and were carried back into the store-house whenever the observers were done with them for the time being. No shelter whatever was built for them.

III.—DESCRIPTION OF INSTRUMENTS.

With the exception of the chronometers, the instruments employed were all my own private property. As they were mostly the same ones that I used at Des Moines, in observing the eclipse of August 7, 1869, all of which are fully described in my report on that eclipse, Appendix II to the Washington Observations for 1867, pp. 26–32, it will only be necessary to give a list of them here, and to mention such changes as were made in them for the present eclipse.

An Achromatic Telescope of 43.58 inches focal length, and 3.01 inches clear aperture, made by Alvan Clark & Sons, of Cambridgeport, Massachusetts. This instrument is provided with a large battery of eye-pieces, ranging in power from 27.2 to 400 diameters. It is equatorially mounted on a very firm, portable tripod stand, which can be adjusted to any latitude, except very low ones, and has a slow motion by which it may be moved through a few degrees in azimuth. The polar and declination axes are both provided with clamp screws; but there are neither divided circles nor tangent screws.

The finder which was originally furnished with this telescope, and which was used at Des Moines, had a clear aperture of only 0.68 of an inch. This seemed to me too small; so I discarded it, and substituted another having an achromatic object-glass of 8.87 inches focus and 1.20 inches clear aperture. It is provided with a direct eye-piece magnifying 10.0 diameters, and a diagonal one magnifying 6.3 diameters. Each of them has a field of view 3° 15′ in diameter. The pointing apparatus is the adjustable needle-point which was used at Des Moines.

A Single-Prism Spectroscope, having the following optical constants:

Small telescope:

Focal distance of object-glass	6.55 inches.
Clear aperture of object-glass	0.86 inch.
Diameter of field of view	5° 33′
Magnifying power	5.71 diameters.

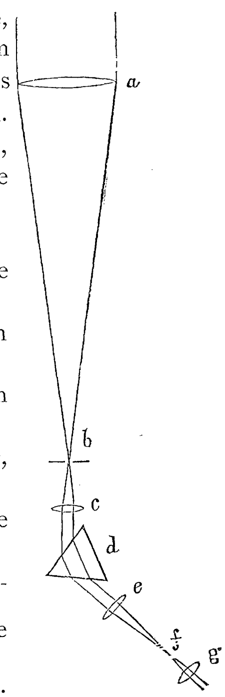
Collimating lens for slit:

Focal distance	6.52 inches.
Clear aperture	0.82 inch.

Collimating lens for scale:	
Focal distance	4.17 inches.
Clear aperture	0.82 inch.
Prism:	
Refracting angle	60° 8′
Minimum deviation of line D	47° 44′
Refractive index	1.613
Density	3.532

It is often desirable to have a formula which will enable us to calculate how much an object is magnified when seen in the field of view of a spectroscope attached to a telscope. In order to obtain such a formula, let us consider a beam of perfectly homogeneous light —that is, light of but a single wave length—falling upon the object-glass of a telescope, *a*, Figure 2. It will be brought to a focus at *b*, and will there form an image between the jaws of the slit situated at that point. Then, passing through the collimating lens *c*, whose principal focus is at *b*, the rays composing the beam will be rendered parallel. Next, falling upon the prism *d*, the beam will be refracted and thrown upon the lens *e*, which will bring it to a focus at *f*, where a second image will be formed. This image will be viewed through the eye-lens *g*.

Fig. 2.



Now let

m = number of diameters which the image seen in the field of view of the spectroscope-telescope is magnified.

F = focal length of object-glass of main telescope—that is, of the lens a in Fig. 2.
